35.8.3 Additional Uncore PMU MSRs in the Intel® Xeon® Processor E5 Family

Intel Xeon Processor E5 family is based on the Sandy Bridge microarchitecture. The MSR-based uncore PMU interfaces are listed in Table 35-19. For complete detail of the uncore PMU, refer to Intel Xeon Processor E5 Product Family Uncore Performance Monitoring Guide. These processors have a CPUID signature with DisplayFamily_DisplayModel of 06_2DH

Table 35-19. Uncore PMU MSRs in Intel® Xeon® Processor E5 Family

Register Address		Register Name	Scope	Bit Description
Hex	Dec			
C08H		MSR_U_PMON_UCLK_FIXED_CTL	Package	Uncore U-box UCLK fixed counter control
C09H		MSR_U_PMON_UCLK_FIXED_CTR	Package	Uncore U-box UCLK fixed counter
C10H		MSR_U_PMON_EVNTSEL0	Package	Uncore U-box perfmon event select for U-box counter 0.
C11H		MSR_U_PMON_EVNTSEL1	Package	Uncore U-box perfmon event select for U-box counter 1.
C16H		MSR_U_PMON_CTR0	Package	Uncore U-box perfmon counter 0
C17H		MSR_U_PMON_CTR1	Package	Uncore U-box perfmon counter 1
C24H		MSR_PCU_PMON_BOX_CTL	Package	Uncore PCU perfmon for PCU-box-wide control
C30H		MSR_PCU_PMON_EVNTSEL0	Package	Uncore PCU perfmon event select for PCU counter 0.
C31H		MSR_PCU_PMON_EVNTSEL1	Package	Uncore PCU perfmon event select for PCU counter 1.
C32H		MSR_PCU_PMON_EVNTSEL2	Package	Uncore PCU perfmon event select for PCU counter 2.
C33H		MSR_PCU_PMON_EVNTSEL3	Package	Uncore PCU perfmon event select for PCU counter 3.
C34H		MSR_PCU_PMON_BOX_FILTER	Package	Uncore PCU perfmon box-wide filter.
C36H		MSR_PCU_PMON_CTR0	Package	Uncore PCU perfmon counter 0.
C37H		MSR_PCU_PMON_CTR1	Package	Uncore PCU perfmon counter 1.
C38H		MSR_PCU_PMON_CTR2	Package	Uncore PCU perfmon counter 2.
C39H		MSR_PCU_PMON_CTR3	Package	Uncore PCU perfmon counter 3.
D04H		MSR_C0_PMON_BOX_CTL	Package	Uncore C-box 0 perfmon local box wide control.
D10H		MSR_C0_PMON_EVNTSEL0	Package	Uncore C-box 0 perfmon event select for C-box 0 counter 0.

Table 35-19. Uncore PMU MSRs in Intel® Xeon® Processor E5 Family (Contd.)

Register Address		Register Name	Scope	Bit Description
Hex	Dec

35.9 MSRS IN THE 3RD GENERATION INTEL® CORE™ PROCESSOR FAMILY (BASED ON INTEL® MICROARCHITECTURE CODE NAME IVY BRIDGE)

The 3rd generation Intel® Core™ processor family and Intel® Xeon® processor E3-1200v2 product family (based on Intel microarchitecture code name Ivy Bridge) supports the MSR interfaces listed in Table 35-16, Table 35-17 and Table 35-20. These processors have a CPUID signature with DisplayFamily_DisplayModel of 06_3AH.

Table 35-20. Additional MSRs Supported by 3rd Generation Intel® Core™ Processors (based on Intel® microarchitecture code name Ivy Bridge)

Register Address		Register Name	Scope	Bit Description
Hex	Dec			
CEH	206	MSR_PLATFORM_INFO	Package	See http://biosbits.org.
		7:0		Reserved.
		15:8	Package	**Maximum Non-Turbo Ratio (R/O)** The is the ratio of the frequency that invariant TSC runs at. Frequency = ratio * 100 MHz.
		27:16		Reserved.
		28	Package	**Programmable Ratio Limit for Turbo Mode (R/O)** When set to 1, indicates that Programmable Ratio Limits for Turbo mode is enabled, and when set to 0, indicates Programmable Ratio Limits for Turbo mode is disabled.
		29	Package	**Programmable TDP Limit for Turbo Mode (R/O)** When set to 1, indicates that TDP Limits for Turbo mode are programmable, and when set to 0, indicates TDP Limit for Turbo mode is not programmable.
		31:30		Reserved.
		32	Package	**Low Power Mode Support (LPM) (R/O)** When set to 1, indicates that LPM is supported, and when set to 0, indicates LPM is not supported.
		34:33	Package	**Number of ConfigTDP Levels (R/O)** 00: Only Base TDP level available. 01: One additional TDP level available. 02: Two additional TDP level available. 11: Reserved
		39:35		Reserved.

Table 35-20. Additional MSRs Supported by 3rd Generation Intel® Core™ Processors (based on Intel® microarchitecture code name Ivy Bridge) (Contd.)

Register Address		Register Name	Scope	Bit Description
Hex	Dec			
		47:40	Package	**Maximum Efficiency Ratio (R/O)** The is the minimum ratio (maximum efficiency) that the processor can operates, in units of 100MHz.
		55:48	Package	**Minimum Operating Ratio (R/O)** Contains the minimum supported operating ratio in units of 100 MHz.
		63:56		Reserved.
E2H	226	MSR_PKG_CST_CONFIG_ CONTROL	Core	**C-State Configuration Control (R/W)** Note: C-state values are processor specific C-state code names, unrelated to MWAIT extension C-state parameters or ACPI C-States. See http://biosbits.org.
		2:0		**Package C-State Limit (R/W)** Specifies the lowest processor-specific C-state code name (consuming the least power). for the package. The default is set as factory-configured package C-state limit. The following C-state code name encodings are supported: 000b: C0/C1 (no package C-sate support) 001b: C2 010b: C6 no retention 011b: C6 retention 100b: C7 101b: C7s 111: No package C-state limit. Note: This field cannot be used to limit package C-state to C3.
		9:3		Reserved.
		10		**I/O MWAIT Redirection Enable (R/W)** When set, will map IO_read instructions sent to IO register specified by MSR_PMG_IO_CAPTURE_BASE to MWAIT instructions
		14:11		Reserved.
		15		**CFG Lock (R/WO)** When set, lock bits 15:0 of this register until next reset.
		24:16		Reserved.
		25		**C3 state auto demotion enable (R/W)** When set, the processor will conditionally demote C6/C7 requests to C3 based on uncore auto-demote information.
		26		**C1 state auto demotion enable (R/W)** When set, the processor will conditionally demote C3/C6/C7 requests to C1 based on uncore auto-demote information.
		27		**Enable C3 undemotion (R/W)** When set, enables undemotion from demoted C3.

Table 35-20. Additional MSRs Supported by 3rd Generation Intel® Core™ Processors (based on Intel® microarchitecture code name Ivy Bridge) (Contd.)

Register Address		Register Name	Scope	Bit Description
Hex	Dec			
		28		**Enable C1 undemotion (R/W)** When set, enables undemotion from demoted C1.
		63:29		Reserved.
648H	1608	MSR_CONFIG_TDP_NOMINAL	Package	**Base TDP Ratio (R/O)**
		7:0		**Config_TDP_Base** Base TDP level ratio to be used for this specific processor (in units of 100 MHz).
		63:8		Reserved.
649H	1609	MSR_CONFIG_TDP_LEVEL1	Package	ConfigTDP Level 1 ratio and power level (R/O)
		14:0		PKG_TDP_LVL1. Power setting for ConfigTDP Level 1.
		15		Reserved
		23:16		Config_TDP_LVL1_Ratio. ConfigTDP level 1 ratio to be used for this specific processor.
		31:24		Reserved
		46:32		PKG_MAX_PWR_LVL1. Max Power setting allowed for ConfigTDP Level 1.
		47		Reserved
		62:48		PKG_MIN_PWR_LVL1. MIN Power setting allowed for ConfigTDP Level 1.
		63		Reserved.
64AH	1610	MSR_CONFIG_TDP_LEVEL2	Package	ConfigTDP Level 2 ratio and power level (R/O)
		14:0		PKG_TDP_LVL2. Power setting for ConfigTDP Level 2.
		15		Reserved
		23:16		Config_TDP_LVL2_Ratio. ConfigTDP level 2 ratio to be used for this specific processor.
		31:24		Reserved

		47		Reserved
		62:48		PKG_MIN_PWR_LVL2. MIN Power setting allowed for ConfigTDP Level 2.
		63		Reserved.
64BH	1611	MSR_CONFIG_TDP_CONTROL	Package	**ConfigTDP Control (R/W)**
		1:0		**TDP_LEVEL (RW/L)** System BIOS can program this field.
		30:2		Reserved.

Table 35-20. Additional MSRs Supported by 3rd Generation Intel® Core™ Processors (based on Intel® microarchitecture code name Ivy Bridge) (Contd.)

Register Address		Register Name	Scope	Bit Description
Hex	Dec			
		31		**Config_TDP_Lock (RW/L)** When this bit is set, the content of this register is locked until a reset.
		63:32		Reserved.
64CH	1612	MSR_TURBO_ACTIVATION_RATIO	Package	**ConfigTDP Control (R/W)**
		7:0		**MAX_NON_TURBO_RATIO (RW/L)** System BIOS can program this field.
		30:8		Reserved.
		31		**TURBO_ACTIVATION_RATIO_Lock (RW/L)** When this bit is set, the content of this register is locked until a reset.
		63:32		Reserved.
See Table 35-16, Table 35-17 for other MSR definitions applicable to processors with CPUID signature 06_3AH				

35.9.1 MSRs In Intel® Xeon® Processor E5 v2 Product Family (Based on Ivy Bridge-E Microarchitecture)

Table 35-21 lists model-specific registers (MSRs) that are specific to the Intel® Xeon® Processor E5 v2 Product Family (based on Ivy Bridge-E microarchitecture). These processors have a CPUID signature with DisplayFamily_DisplayModel of 06_3EH, see Table 35-1. These processors supports the MSR interfaces listed in Table 35-16, and Table 35-21.

Table 35-21. MSRs Supported by Intel® Xeon® Processors E5 v2 Product Family (based on Ivy Bridge-E microarchitecture)

Register Address		Register Name	Scope	Bit Description
Hex	Dec			
4EH	78	MSR_PPIN_CTL	Package	Protected Processor Inventory Number Enable Control (R/W)
		0		LockOut (R/WO) Set 1to prevent further writes to MSR_PPIN_CTL. Writing 1 to MSR_PPINCTL[bit 0] is permitted only if MSR_PPIN_CTL[bit 1] is clear, Default is 0. BIOS should provide an opt-in menu to enable the user to turn on MSR_PPIN_CTL[bit 1] for privileged inventory initialization agent to access MSR_PPIN. After reading MSR_PPIN, the privileged inventory initialization agent should write '01b' to MSR_PPIN_CTL to disable further access to MSR_PPIN and prevent unauthorized modification to MSR_PPIN_CTL.

Table 35-21. MSRs Supported by Intel® Xeon® Processors E5 v2 Product Family (based on Ivy Bridge-E microarchitecture) (Contd.)

Register Address		Register Name	Scope	Bit Description
Hex	Dec			
		1		Enable_PPIN (R/W) If 1, enables MSR_PPIN to be accessible using RDMSR. Once set, attempt to write 1 to MSR_PPIN_CTL[bit 0] will cause #GP. If 0, an attempt to read MSR_PPIN will cause #GP. Default is 0.
		63:2		Reserved.
4FH	79	MSR_PPIN	Package	Protected Processor Inventory Number (R/O)
		63:0		**Protected Processor Inventory Number (R/O)** A unique value within a given CPUID family/model/stepping signature that a privileged inventory initialization agent can access to identify each physical processor, when access to MSR_PPIN is enabled. Access to MSR_PPIN is permitted only if MSR_PPIN_CTL[bits 1:0] = '10b'
CEH	206	MSR_PLATFORM_INFO	Package	See http://biosbits.org.
		7:0		Reserved.
		15:8	Package	**Maximum Non-Turbo Ratio (R/O)** The is the ratio of the frequency that invariant TSC runs at. Frequency = ratio * 100 MHz.
		22:16		Reserved.
		23	Package	**PPIN_CAP (R/O)** When set to 1, indicates that Protected Processor Inventory Number (PPIN) capability can be enabled for privileged system inventory agent to read PPIN from MSR_PPIN. When set to 0, PPIN capability is not supported. An attempt to access MSR_PPIN_CTL or MSR_PPIN will cause #GP.
		27:24		Reserved.
		28	Package	**Programmable Ratio Limit for Turbo Mode (R/O)** When set to 1, indicates that Programmable Ratio Limits for Turbo mode is enabled, and when set to 0, indicates Programmable Ratio Limits for Turbo mode is disabled.
		29	Package	**Programmable TDP Limit for Turbo Mode (R/O)** When set to 1, indicates that TDP Limits for Turbo mode are programmable, and when set to 0, indicates TDP Limit for Turbo mode is not programmable.
		39:30		Reserved.
		47:40	Package	**Maximum Efficiency Ratio (R/O)** The is the minimum ratio (maximum efficiency) that the processor can operates, in units of 100MHz.
		63:48		Reserved.

Table 35-21. MSRs Supported by Intel® Xeon® Processors E5 v2 Product Family (based on Ivy Bridge-E microarchitecture) (Contd.)

Register Address		Register Name	Scope	Bit Description

See Table 35-16, Table 35-21 for other MSR definitions applicable to Intel Xeon processor E7 v2 with CPUID signature 06_3AH				

NOTES:

1. An override configuration lower than the factory-set configuration is always supported. An override configuration higher than the factory-set configuration is dependent on features specific to the processor and the platform.

35.9.3 Additional Uncore PMU MSRs in the Intel® Xeon® Processor E5 v2 and E7 v2 Families

Intel Xeon Processor E5 v2 and E7 v2 families are based on the Ivy Bridge-E microarchitecture. The MSR-based uncore PMU interfaces are listed in Table 35-19 and Table 35-23. For complete detail of the uncore PMU, refer to Intel Xeon Processor E5 v2 Product Family Uncore Performance Monitoring Guide. These processors have a CPUID signature with DisplayFamily_DisplayModel of 06_3EH.

35.10 MSRS IN THE 4TH GENERATION INTEL® CORE™ PROCESSORS (BASED ON HASWELL MICROARCHITECTURE)

The 4th generation Intel® Core™ processor family and Intel® Xeon® processor E3-1200v3 product family (based on Haswell microarchitecture), with CPUID DisplayFamily_DisplayModel signature 06_3CH/06_45H/06_46H, support the MSR interfaces listed in Table 35-16, Table 35-17, and Table 35-24. For an MSR listed in Table 35-16 that also appears in Table 35-24, Table 35-24 supercede Table 35-16.

The MSRs listed in Table 35-24 also apply to processors based on Haswell-E microarchitecture (see Section 35.11).

Table 35-24. Additional MSRs Supported by Processors based on the Haswell or Haswell-E microarchitectures

Register Address		Register Name	Scope	Bit Description
Hex	Dec			
3BH	59	IA32_TSC_ADJUST	THREAD	**Per-Logical-Processor TSC ADJUST (R/W)** See Table 35-2.
CEH	206	MSR_PLATFORM_INFO	Package	
		7:0		Reserved.
		15:8	Package	**Maximum Non-Turbo Ratio (R/O)** The is the ratio of the frequency that invariant TSC runs at. Frequency = ratio * 100 MHz.
		27:16		Reserved.

Table 35-24. Additional MSRs Supported by Processors based on the Haswell or Haswell-E microarchitectures

Register Address		Register Name	Scope	Bit Description
Hex	Dec			
		28	Package	**Programmable Ratio Limit for Turbo Mode (R/O)** When set to 1, indicates that Programmable Ratio Limits for Turbo mode is enabled, and when set to 0, indicates Programmable Ratio Limits for Turbo mode is disabled.
		29	Package	**Programmable TDP Limit for Turbo Mode (R/O)** When set to 1, indicates that TDP Limits for Turbo mode are programmable, and when set to 0, indicates TDP Limit for Turbo mode is not programmable.
		31:30		Reserved.
		32	Package	**Low Power Mode Support (LPM) (R/O)** When set to 1, indicates that LPM is supported, and when set to 0, indicates LPM is not supported.
		34:33	Package	**Number of ConfigTDP Levels (R/O)** 00: Only Base TDP level available. 01: One additional TDP level available. 02: Two additional TDP level available. 11: Reserved
		39:35		Reserved.
		47:40	Package	**Maximum Efficiency Ratio (R/O)** The is the minimum ratio (maximum efficiency) that the processor can operates, in units of 100MHz.
		55:48	Package	**Minimum Operating Ratio (R/O)** Contains the minimum supported operating ratio in units of 100 MHz.
		63:56		Reserved.
186H	390	IA32_PERFEVTSEL0	THREAD	**Performance Event Select for Counter 0 (R/W)** Supports all fields described inTable 35-2 and the fields below.
		32		IN_TX: see Section 18.10.5.1 When IN_TX (bit 32) is set, AnyThread (bit 21) should be cleared to prevent incorrect results
187H	391	IA32_PERFEVTSEL1	THREAD	**Performance Event Select for Counter 1 (R/W)** Supports all fields described inTable 35-2 and the fields below.
		32		IN_TX: see Section 18.10.5.1 When IN_TX (bit 32) is set, AnyThread (bit 21) should be cleared to prevent incorrect results
188H	392	IA32_PERFEVTSEL2	THREAD	**Performance Event Select for Counter 2 (R/W)** Supports all fields described inTable 35-2 and the fields below.
		32		IN_TX: see Section 18.10.5.1 When IN_TX (bit 32) is set, AnyThread (bit 21) should be cleared to prevent incorrect results

Table 35-24. Additional MSRs Supported by Processors based on the Haswell or Haswell-E microarchitectures

Register Address		Register Name	Scope	Bit Description
Hex	Dec			
		33		IN_TXCP: see Section 18.10.5.1 When IN_TXCP=1 & IN_TX=1 and in sampling, spurious PMI may occur and transactions may continuously abort near overflow conditions. Software should favor using IN_TXCP for counting over sampling. If sampling, software should use large "sample-after" value after clearing the counter configured to use IN_TXCP and also always reset the counter even when no overflow condition was reported.
189H	393	IA32_PERFEVTSEL3	THREAD	**Performance Event Select for Counter 3 (R/W)** Supports all fields described inTable 35-2 and the fields below.
		32		IN_TX: see Section 18.10.5.1 When IN_TX (bit 32) is set, AnyThread (bit 21) should be cleared to prevent incorrect results
1D9H	473	IA32_DEBUGCTL	Thread	**Debug Control (R/W)** See Table 35-2.
		0		**LBR: Last Branch Record**
		1		**BTF**
		5:2		Reserved.
		6		**TR: Branch Trace**
		7		**BTS: Log Branch Trace Message to BTS buffer**

		3:0	Package	**Power Units** See Section 14.9.1, "RAPL Interfaces."
		7:4	Package	**Reserved**
		12:8	Package	**Energy Status Units** Energy related information (in Joules) is based on the multiplier, 1/2^ESU; where ESU is an unsigned integer represented by bits 12:8. Default value is 0EH (or 61 micro-joules)
		15:13	Package	**Reserved**
		19:16	Package	**Time Units** See Section 14.9.1, "RAPL Interfaces."
		63:20		Reserved
690H	1680	MSR_CORE_PERF_LIMIT_REASONS	Package	**Indicator of Frequency Clipping in Processor Cores (R/W) (frequency refers to processor core frequency)**
		0		**PROCHOT Status (R0)** When set, processor core frequency is reduced below the operating system request due to assertion of external PROCHOT.

Table 35-27. Additional MSRs Supported by Intel® Xeon® Processor E5 v3 Family

Register Address		Register Name	Scope	Bit Description
Hex	Dec			
		1		**Thermal Status (R0)** When set, frequency is reduced below the operating system request due to a thermal event.
		2		**Power Budget Management Status (R0)** When set, frequency is reduced below the operating system request due to PBM limit
		3		**Platform Configuration Services Status (R0)** When set, frequency is reduced below the operating system request due to PCS limit
		4		Reserved.
		5		**Autonomous Utilization-Based Frequency Control Status (R0)** When set, frequency is reduced below the operating system request because the processor has detected that utilization is low
		6		**VR Therm Alert Status (R0)** When set, frequency is reduced below the operating system request due to a thermal alert from the Voltage Regulator.
		7		Reserved.
		8		**Electrical Design Point Status (R0)** When set, frequency is reduced below the operating system request due to electrical design point constraints (e.g. maximum electrical current consumption).
		9		Reserved.
		10		**Multi-Core Turbo Status (R0)** When set, frequency is reduced below the operating system request due to Multi-Core Turbo limits
		12:11		Reserved.
		13		**Core Frequency P1 Status (R0)** When set, frequency is reduced below max non-turbo P1
		14		**Core Max n-core Turbo Frequency Limiting Status (R0)** When set, frequency is reduced below max n-core turbo frequency
		15		**Core Frequency Limiting Status (R0)** When set, frequency is reduced below the operating system request.
		16		**PROCHOT Log** When set, indicates that the PROCHOT Status bit has asserted since the log bit was last cleared. This log bit will remain set until cleared by software writing 0.
		17		**Thermal Log** When set, indicates that the Thermal Status bit has asserted since the log bit was last cleared. This log bit will remain set until cleared by software writing 0.

Table 35-27. Additional MSRs Supported by Intel® Xeon® Processor E5 v3 Family

Register Address		Register Name	Scope	Bit Description
Hex	Dec			
		18		**Power Budget Management Log** When set, indicates that the PBM Status bit has asserted since the log bit was last cleared. This log bit will remain set until cleared by software writing 0.
		19		**Platform Configuration Services Log** When set, indicates that the PCS Status bit has asserted since the log bit was last cleared. This log bit will remain set until cleared by software writing 0.
		20		Reserved.
		21		**Autonomous Utilization-Based Frequency Control Log** When set, indicates that the AUBFC Status bit has asserted since the log bit was last cleared. This log bit will remain set until cleared by software writing 0.
		22		**VR Therm Alert Log** When set, indicates that the VR Therm Alert Status bit has asserted since the log bit was last cleared. This log bit will remain set until cleared by software writing 0.
		23		Reserved.
		24		**Electrical Design Point Log** When set, indicates that the EDP Status bit has asserted since the log bit was last cleared. This log bit will remain set until cleared by software writing 0.
		25		Reserved.
		26		**Multi-Core Turbo Log** When set, indicates that the Multi-Core Turbo Status bit has asserted since the log bit was last cleared. This log bit will remain set until cleared by software writing 0.
		28:27		Reserved.
		29		**Core Frequency P1 Log** When set, indicates that the Core Frequency P1 Status bit has asserted since the log bit was last cleared. This log bit will remain set until cleared by software writing 0.
		30		**Core Max n-core Turbo Frequency Limiting Log** When set, indicates that the Core Max n-core Turbo Frequency Limiting Status bit has asserted since the log bit was last cleared. This log bit will remain set until cleared by software writing 0.
		31		**Core Frequency Limiting Log** When set, indicates that the Core Frequency Limiting Status bit has asserted since the log bit was last cleared. This log bit will remain set until cleared by software writing 0.
		63:32		Reserved.

Table 35-27. Additional MSRs Supported by Intel® Xeon® Processor E5 v3 Family

Register Address		Register Name	Scope	Bit Description
Hex	Dec			
C8DH	3213	IA32_QM_EVTSEL	THREAD	**Monitoring Event Select Register (R/W).** if CPUID.(EAX=07H, ECX=0):EBX.PQM[bit 12] = 1
		7:0		**EventID (RW)** **Event encoding:** **0x0: no monitoring** **0x1: L3 occupancy monitoring** **all other encoding reserved.**

		61:0		**Resource Monitored Data**
		62		**Unavailable**: If 1, indicates data for this RMID is not available or not monitored for this resource or RMID.
		63		**Error:** If 1, indicates and unsupported RMID or event type was written to IA32_PQR_QM_EVTSEL.
C8FH	3215	IA32_PQR_ASSOC	THREAD	**Resource Association Register (R/W).**
		9:0		**RMID**
		63: 10		**Reserved**
See Table 35-16, Table 35-21, Table 35-24 for other MSR definitions applicable to processors with CPUID signature 06_3FH				

NOTES:

1. An override configuration lower than the factory-set configuration is always supported. An override configuration higher than the factory-set configuration is dependent on features specific to the processor and the platform.

35.11.1 Additional Uncore PMU MSRs in the Intel® Xeon® Processor E5 v3 Family

Intel Xeon Processor E5 v3 and E7 v3 family are based on the Haswell-E microarchitecture. The MSR-based uncore PMU interfaces are listed in Table 35-28. For complete detail of the uncore PMU, refer to Intel Xeon Processor E5 v3 Product Family Uncore Performance Monitoring Guide. These processors have a CPUID signature with DisplayFamily_DisplayModel of 06_3FH.

Table 35-28. Uncore PMU MSRs in Intel® Xeon® Processor E5 v3 Family

Register Address		Register Name	Scope	Bit Description
Hex	Dec			
700H		MSR_PMON_GLOBAL_CTL	Package	Uncore perfmon per-socket global control.
701H		MSR_PMON_GLOBAL_STATUS	Package	Uncore perfmon per-socket global status.
702H		MSR_PMON_GLOBAL_CONFIG	Package	Uncore perfmon per-socket global configuration.
703H		MSR_U_PMON_UCLK_FIXED_CTL	Package	Uncore U-box UCLK fixed counter control

Register Address		Register Name	Scope	Bit Description
Hex	Dec			
704H		MSR_U_PMON_UCLK_FIXED_CTR	Package	Uncore U-box UCLK fixed counter
705H		MSR_U_PMON_EVNTSEL0	Package	Uncore U-box perfmon event select for U-box counter 0.
706H		MSR_U_PMON_EVNTSEL1	Package	Uncore U-box perfmon event select for U-box counter 1.
708H		MSR_U_PMON_BOX_STATUS	Package	Uncore U-box perfmon U-box wide status.
709H		MSR_U_PMON_CTR0	Package	Uncore U-box perfmon counter 0
70AH		MSR_U_PMON_CTR1	Package	Uncore U-box perfmon counter 1
710H		MSR_PCU_PMON_BOX_CTL	Package	Uncore PCU perfmon for PCU-box-wide control
711H		MSR_PCU_PMON_EVNTSEL0	Package	Uncore PCU perfmon event select for PCU counter 0.
712H		MSR_PCU_PMON_EVNTSEL1	Package	Uncore PCU perfmon event select for PCU counter 1.
713H		MSR_PCU_PMON_EVNTSEL2	Package	Uncore PCU perfmon event select for PCU counter 2.
714H		MSR_PCU_PMON_EVNTSEL3	Package	Uncore PCU perfmon event select for PCU counter 3.
715H		MSR_PCU_PMON_BOX_FILTER	Package	Uncore PCU perfmon box-wide filter.
716H		MSR_PCU_PMON_BOX_STATUS	Package	Uncore PCU perfmon box wide status.
717H		MSR_PCU_PMON_CTR0	Package	Uncore PCU perfmon counter 0.
718H		MSR_PCU_PMON_CTR1	Package	Uncore PCU perfmon counter 1.
719H		MSR_PCU_PMON_CTR2	Package	Uncore PCU perfmon counter 2.
71AH		MSR_PCU_PMON_CTR3	Package	Uncore PCU perfmon counter 3.
720H		MSR_S0_PMON_BOX_CTL	Package	Uncore SBo 0 perfmon for SBo 0 box-wide control
721H		MSR_S0_PMON_EVNTSEL0	Package	Uncore SBo 0 perfmon event select for SBo 0 counter 0.
722H		MSR_S0_PMON_EVNTSEL1	Package	Uncore SBo 0 perfmon event select for SBo 0 counter 1.
723H		MSR_S0_PMON_EVNTSEL2	Package	Uncore SBo 0 perfmon event select for SBo 0 counter 2.
724H		MSR_S0_PMON_EVNTSEL3	Package	Uncore SBo 0 perfmon event select for SBo 0 counter 3.
725H		MSR_S0_PMON_BOX_FILTER	Package	Uncore SBo 0 perfmon box-wide filter.
726H		MSR_S0_PMON_CTR0	Package	Uncore SBo 0 perfmon counter 0.
727H		MSR_S0_PMON_CTR1	Package	Uncore SBo 0 perfmon counter 1.
728H		MSR_S0_PMON_CTR2	Package	Uncore SBo 0 perfmon counter 2.
729H		MSR_S0_PMON_CTR3	Package	Uncore SBo 0 perfmon counter 3.
72AH		MSR_S1_PMON_BOX_CTL	Package	Uncore SBo 1 perfmon for SBo 1 box-wide control
72BH		MSR_S1_PMON_EVNTSEL0	Package	Uncore SBo 1 perfmon event select for SBo 1 counter 0.
72CH		MSR_S1_PMON_EVNTSEL1	Package	Uncore SBo 1 perfmon event select for SBo 1 counter 1.
72DH		MSR_S1_PMON_EVNTSEL2	Package	Uncore SBo 1 perfmon event select for SBo 1 counter 2.
72EH		MSR_S1_PMON_EVNTSEL3	Package	Uncore SBo 1 perfmon event select for SBo 1 counter 3.
72FH		MSR_S1_PMON_BOX_FILTER	Package	Uncore SBo 1 perfmon box-wide filter.
730H		MSR_S1_PMON_CTR0	Package	Uncore SBo 1 perfmon counter 0.
731H		MSR_S1_PMON_CTR1	Package	Uncore SBo 1 perfmon counter 1.
732H		MSR_S1_PMON_CTR2	Package	Uncore SBo 1 perfmon counter 2.
733H		MSR_S1_PMON_CTR3	Package	Uncore SBo 1 perfmon counter 3.

35.12 MSRS IN INTEL® CORE™ M PROCESSORS AND 5TH GENERATION INTEL CORE PROCESSORS

The Intel® Core™ M-5xxx processors and 5th generation Intel® Core™ Processors, and Intel® Xeon® Processor E3-1200 v4 family are based on the Broadwell microarchitecture. The Intel® Core™ M-5xxx processors and 5th generation Intel® Core™ Processors have CPUID DisplayFamily_DisplayModel signature 06_3DH. Intel® Xeon® Processor E3-1200 v4 family and the 5th generation Intel® Core™ Processors have CPUID DisplayFamily_DisplayModel signature 06_47H. Processors with signatures 06_3DH and 06_47H support the MSR interfaces listed in Table 35-16, Table 35-17, Table 35-20, Table 35-24, Table 35-25, Table 35-29, and Table 35-30. For an MSR listed in Table 35-30 that also appears in the model-specific tables of prior generations, Table 35-30 supercede prior generation tables.

Table 35-29 lists MSRs that are common to processors based on the Broadwell microarchitectures (including CPUID signatures 06_3DH, 06_47H, 06_4FH, and 06_56H).

35.14 MSRS IN THE 6TH GENERATION INTEL® CORE™ PROCESSORS

The 6th generation Intel® Core™ processor family is based on the Skylake microarchitecture. They have CPUID DisplayFamily_DisplayModel signatures of 06_4EH and 06_5EH, supports the MSR interfaces listed in Table 35-16, Table 35-17, Table 35-20, Table 35-24, Table 35-30, and Table 35-32. For an MSR listed in Table 35-32 that also appears in the model-specific tables of prior generations, Table 35-32 supercede prior generation tables.

35.15 MSRS IN THE NEXT GENERATION INTEL® XEON PHI™ PROCESSORS

The next generation Intel® Xeon Phi™ processor family, with CPUID DisplayFamily_DisplayModel signature 06_57H, supports the MSR interfaces listed in Table 35-33. These processors are based on the Knights Landing microarchitecture. Some MSRs are shared between a pair of processor cores, the scope is marked as module.

Table 35-33. Selected MSRs Supported by Next Generation Intel® Xeon Phi™ Processors with DisplayFamily_DisplayModel Signature 06_57H

Address		Register Name	Scope	Bit Description
Hex	Dec			
0H	0	IA32_P5_MC_ADDR	Module	See Section 35.20, "MSRs in Pentium Processors."
1H	1	IA32_P5_MC_TYPE	Module	See Section 35.20, "MSRs in Pentium Processors."
6H	6	IA32_MONITOR_FILTER_ SIZE	Thread	See Section 8.10.5, "Monitor/Mwait Address Range Determination." andTable 35-2
10H	16	IA32_TIME_STAMP_ COUNTER	Thread	See Section 17.14, "Time-Stamp Counter," and see Table 35-2.
17H	23	IA32_PLATFORM_ID	Package	**Platform ID (R)** See Table 35-2.
1BH	27	IA32_APIC_BASE	Thread	See Section 10.4.4, "Local APIC Status and Location," and Table 35-2.
34H	52	MSR_SMI_COUNT	Thread	**SMI Counter (R/O)**
		31:0		**SMI Count (R/O)**
		63:32		Reserved.
3AH	58	IA32_FEATURE_CONTROL	Thread	**Control Features in Intel 64Processor (R/W)** See Table 35-2.
		0		**Lock (R/WL)**
		1		**Reserved**
		2		**Enable VMX outside SMX operation (R/WL)**
3BH	59	IA32_TSC_ADJUST	THREAD	**Per-Logical-Processor TSC ADJUST (R/W)** See Table 35-2.
79H	121	IA32_BIOS_UPDT_TRIG	Core	**BIOS Update Trigger Register (W)** See Table 35-2.
8BH	139	IA32_BIOS_SIGN_ID	THREAD	**BIOS Update Signature ID (RO)** See Table 35-2.
C1H	193	IA32_PMC0	THREAD	**Performance counter register** See Table 35-2.
C2H	194	IA32_PMC1	THREAD	**Performance Counter Register** See Table 35-2.
CEH	206	MSR_PLATFORM_INFO	Package	See http://biosbits.org.
		7:0		Reserved.
		15:8	Package	**Maximum Non-Turbo Ratio (R/O)** The is the ratio of the frequency that invariant TSC runs at. Frequency = ratio * 100 MHz.
		27:16		Reserved.
		28	Package	**Programmable Ratio Limit for Turbo Mode (R/O)** When set to 1, indicates that Programmable Ratio Limits for Turbo mode is enabled, and when set to 0, indicates Programmable Ratio Limits for Turbo mode is disabled.

Table 35-33. Selected MSRs Supported by Next Generation Intel® Xeon Phi™ Processors with DisplayFamily_DisplayModel Signature 06_57H

Address		Register Name	Scope	Bit Description
Hex	Dec			
		29	Package	**Programmable TDP Limit for Turbo Mode (R/O)** When set to 1, indicates that TDP Limits for Turbo mode are programmable, and when set to 0, indicates TDP Limit for Turbo mode is not programmable.
		39:30		Reserved.
		47:40	Package	**Maximum Efficiency Ratio (R/O)** The is the minimum ratio (maximum efficiency) that the processor can operates, in units of 100MHz.
		63:48		Reserved.
E2H	226	MSR_PKG_CST_CONFIG_ CONTROL	Module	**C-State Configuration Control (R/W)**
		2:0		**Package C-State Limit (R/W)** The following C-state code name encodings are supported: 000b: C0/C1 001b: C2 010b: C6 No Retention 011b: C6 Retention 111b: No limit
		9:3		Reserved.
		10		**I/O MWAIT Redirection Enable (R/W)**
		14:11		Reserved.
		15		**CFG Lock (R/WO)**
		63:16		Reserved.
E4H	228	MSR_PMG_IO_CAPTURE_ BASE	Module	**Power Management IO Redirection in C-state (R/W)**
		15:0		**LVL_2 Base Address (R/W)**
		18:16		**C-state Range (R/W)** Specifies the encoding value of the maximum C-State code name to be included when IO read to MWAIT redirection is enabled by MSR_PKG_CST_CONFIG_CONTROL[bit10]: 100b - C4 is the max C-State to include 110b - C6 is the max C-State to include
		63:19		Reserved.
E7H	231	IA32_MPERF	Thread	**Maximum Performance Frequency Clock Count (RW)** See Table 35-2.
E8H	232	IA32_APERF	Thread	**Actual Performance Frequency Clock Count (RW)** See Table 35-2.
FEH	254	IA32_MTRRCAP	Core	**Memory Type Range Register (R)** See Table 35-2.

Table 35-33. Selected MSRs Supported by Next Generation Intel® Xeon Phi™ Processors with DisplayFamily_DisplayModel Signature 06_57H

Address		Register Name	Scope	Bit Description
Hex	Dec			
13CH	52	MSR_FEATURE_CONFIG	Core	**AES Configuration (RW-L)** Privileged post-BIOS agent must provide a #GP handler to handle unsuccessful read of this MSR.
		1:0		**AES Configuration (RW-L)** Upon a successful read of this MSR, the configuration of AES instruction set availability is as follows: 11b: AES instructions are not available until next RESET. otherwise, AES instructions are available. Note, AES instruction set is not available if read is unsuccessful. If the configuration is not 01b, AES instruction can be mis-configured if a privileged agent unintentionally writes 11b.
		63:2		Reserved.
174H	372	IA32_SYSENTER_CS	Thread	See Table 35-2.
175H	373	IA32_SYSENTER_ESP	Thread	See Table 35-2.
176H	374	IA32_SYSENTER_EIP	Thread	See Table 35-2.
179H	377	IA32_MCG_CAP	Thread	See Table 35-2.
17AH	378	IA32_MCG_STATUS	Thread	See Table 35-2.
186H	390	IA32_PERFEVTSEL0	Thread	Performance Monitoring Event Select Register (R/W) See Table 35-2.
		7:0		**Event Select**

821H	2081	IA32_X2APIC_IRR1	Thread	x2APIC Interrupt Request register bits [63:32] (R/0)
822H	2082	IA32_X2APIC_IRR2	Thread	x2APIC Interrupt Request register bits [95:64] (R/0)
823H	2083	IA32_X2APIC_IRR3	Thread	x2APIC Interrupt Request register bits [127:96] (R/0)
824H	2084	IA32_X2APIC_IRR4	Thread	x2APIC Interrupt Request register bits [159:128] (R/0)
825H	2085	IA32_X2APIC_IRR5	Thread	x2APIC Interrupt Request register bits [191:160] (R/0)
826H	2086	IA32_X2APIC_IRR6	Thread	x2APIC Interrupt Request register bits [223:192] (R/0)
827H	2087	IA32_X2APIC_IRR7	Thread	x2APIC Interrupt Request register bits [255:224] (R/0)
828H	2088	IA32_X2APIC_ESR	Thread	x2APIC Error Status register (R/W)
82FH	2095	IA32_X2APIC_LVT_CMCI	Thread	x2APIC LVT Corrected Machine Check Interrupt register (R/W)
830H	2096	IA32_X2APIC_ICR	Thread	x2APIC Interrupt Command register (R/W)
832H	2098	IA32_X2APIC_LVT_TIMER	Thread	x2APIC LVT Timer Interrupt register (R/W)
833H	2099	IA32_X2APIC_LVT_THERMAL	Thread	x2APIC LVT Thermal Sensor Interrupt register (R/W)
834H	2100	IA32_X2APIC_LVT_PMI	Thread	x2APIC LVT Performance Monitor register (R/W)
835H	2101	IA32_X2APIC_LVT_LINT0	Thread	x2APIC LVT LINT0 register (R/W)
836H	2102	IA32_X2APIC_LVT_LINT1	Thread	x2APIC LVT LINT1 register (R/W)
837H	2103	IA32_X2APIC_LVT_ERROR	Thread	x2APIC LVT Error register (R/W)
838H	2104	IA32_X2APIC_INIT_COUNT	Thread	x2APIC Initial Count register (R/W)
839H	2105	IA32_X2APIC_CUR_COUNT	Thread	x2APIC Current Count register (R/O)
83EH	2110	IA32_X2APIC_DIV_CONF	Thread	x2APIC Divide Configuration register (R/W)
83FH	2111	IA32_X2APIC_SELF_IPI	Thread	x2APIC Self IPI register (W/O)
C000_0080H		IA32_EFER	Thread	**Extended Feature Enables** See Table 35-2.
C000_0081H		IA32_STAR	Thread	**System Call Target Address (R/W)** See Table 35-2.
C000_0082H		IA32_LSTAR	Thread	**IA-32e Mode System Call Target Address (R/W)** See Table 35-2.
C000_0084H		IA32_FMASK	Thread	**System Call Flag Mask (R/W)** See Table 35-2.

Table 35-33. Selected MSRs Supported by Next Generation Intel® Xeon Phi™ Processors with DisplayFamily_DisplayModel Signature 06_57H

Address		Register Name	Scope	Bit Description
Hex	Dec			
C000_0100H		IA32_FS_BASE	Thread	**Map of BASE Address of FS (R/W)** See Table 35-2.
C000_0101H		IA32_GS_BASE	Thread	**Map of BASE Address of GS (R/W)** See Table 35-2.
C000_0102H		IA32_KERNEL_GSBASE	Thread	**Swap Target of BASE Address of GS (R/W)** See Table 35-2.
C000_0103H		IA32_TSC_AUX	Thread	**AUXILIARY TSC Signature. (R/W)** See Table 35-2

35.16 MSRS IN THE PENTIUM® 4 AND INTEL® XEON® PROCESSORS

Table 35-34 lists MSRs (architectural and model-specific) that are defined across processor generations based on Intel NetBurst microarchitecture. The processor can be identified by its CPUID signatures of DisplayFamily encoding of 0FH, see Table 35-1.

- MSRs with an "IA32_" prefix are designated as "architectural." This means that the functions of these MSRs and their addresses remain the same for succeeding families of IA-32 processors.
- MSRs with an "MSR_" prefix are model specific with respect to address functionalities. The column "Model Availability" lists the model encoding value(s) within the Pentium 4 and Intel Xeon processor family at the specified register address. The model encoding value of a processor can be queried using CPUID. See "CPUID—CPU Identification" in Chapter 3 of the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 2A*.

Table 35-34. MSRs in the Pentium® 4 and Intel® Xeon® Processors

Register Address		Register Name Fields and Flags	Model Availability	Shared/ Unique[1]	Bit Description
Hex	Dec				
0H	0	IA32_P5_MC_ADDR	0, 1, 2, 3, 4, 6	Shared	See Section 35.20, "MSRs in Pentium Processors."
1H	1	IA32_P5_MC_TYPE	0, 1, 2, 3, 4, 6	Shared	See Section 35.20, "MSRs in Pentium Processors."
6H	6	IA32_MONITOR_FILTER_LINE_SIZE	3, 4, 6	Shared	See Section 8.10.5, "Monitor/Mwait Address Range Determination."
10H	16	IA32_TIME_STAMP_COUNTER	0, 1, 2, 3, 4, 6	Unique	**Time Stamp Counter** See Table 35-2.
					On earlier processors, only the lower 32 bits are writable. On any write to the lower 32 bits, the upper 32 bits are cleared. For processor family 0FH, models 3 and 4: all 64 bits are writable.
17H	23	IA32_PLATFORM_ID	0, 1, 2, 3, 4, 6	Shared	**Platform ID (R)** See Table 35-2. The operating system can use this MSR to determine "slot" information for the processor and the proper microcode update to load.

Table 35-34. MSRs in the Pentium® 4 and Intel® Xeon® Processors (Contd.)

Register Address		Register Name Fields and Flags	Model Avail-ability	Shared/ Unique[1]	Bit Description
Hex	Dec				
1BH	27	IA32_APIC_BASE	0, 1, 2, 3, 4, 6	Unique	**APIC Location and Status (R/W)** See Table 35-2. See Section 10.4.4, "Local APIC Status and Location."
2AH	42	MSR_EBC_HARD_POWERON	0, 1, 2, 3, 4, 6	Shared	**Processor Hard Power-On Configuration** **(R/W)** Enables and disables processor features; **(R)** indicates current processor configuration.
		0			**Output Tri-state Enabled (R)** Indicates whether tri-state output is enabled (1) or disabled (0) as set by the strapping of SMI#. The value in this bit is written on the deassertion of RESET#; the bit is set to 1 when the address bus signal is asserted.
		1			**Execute BIST (R)** Indicates whether the execution of the BIST is enabled (1) or disabled (0) as set by the strapping of INIT#. The value in this bit is written on the deassertion of RESET#; the bit is set to 1 when the address bus signal is asserted.
		2			**In Order Queue Depth (R)** Indicates whether the in order queue depth for the system bus is 1 (1) or up to 12 (0) as set by the strapping of A7#. The value in this bit is written on the deassertion of RESET#; the bit is set to 1 when the address bus signal is asserted.
		3			**MCERR# Observation Disabled (R)** Indicates whether MCERR# observation is enabled (0) or disabled (1) as determined by the strapping of A9#. The value in this bit is written on the deassertion of RESET#; the bit is set to 1 when the address bus signal is asserted.
		4			**BINIT# Observation Enabled (R)** Indicates whether BINIT# observation is enabled (0) or disabled (1) as determined by the strapping of A10#. The value in this bit is written on the deassertion of RESET#; the bit is set to 1 when the address bus signal is asserted.
		6:5			**APIC Cluster ID (R)** Contains the logical APIC cluster ID value as set by the strapping of A12# and A11#. The logical cluster ID value is written into the field on the deassertion of RESET#; the field is set to 1 when the address bus signal is asserted.

Table 35-34. MSRs in the Pentium® 4 and Intel® Xeon® Processors (Contd.)

Register Address		Register Name Fields and Flags	Model Avail-ability	Shared/ Unique[1]	Bit Description
Hex	Dec				
		7			**Bus Park Disable (R)** Indicates whether bus park is enabled (0) or disabled (1) as set by the strapping of A15#. The value in this bit is written on the deassertion of RESET#; the bit is set to 1 when the address bus signal is asserted.
		11:8			Reserved.
		13:12			**Agent ID (R)** Contains the logical agent ID value as set by the strapping of BR[3:0]. The logical ID value is written into the field on the deassertion of RESET#; the field is set to 1 when the address bus signal is asserted.
		63:14			Reserved.
2BH	43	MSR_EBC_SOFT_POWERON	0, 1, 2, 3, 4, 6	Shared	**Processor Soft Power-On Configuration (R/W)** Enables and disables processor features.
		0			**RCNT/SCNT On Request Encoding Enable (R/W)** Controls the driving of RCNT/SCNT on the request encoding. Set to enable (1); clear to disabled (0, default).
		1			**Data Error Checking Disable (R/W)** Set to disable system data bus parity checking; clear to enable parity checking.
		2			**Response Error Checking Disable (R/W)** Set to disable (default); clear to enable.
		3			**Address/Request Error Checking Disable (R/W)** Set to disable (default); clear to enable.
		4			**Initiator MCERR# Disable (R/W)** Set to disable MCERR# driving for initiator bus requests (default); clear to enable.
		5			**Internal MCERR# Disable (R/W)** Set to disable MCERR# driving for initiator internal errors (default); clear to enable.
		6			**BINIT# Driver Disable (R/W)** Set to disable BINIT# driver (default); clear to enable driver.
		63:7			Reserved.

Table 35-34. MSRs in the Pentium® 4 and Intel® Xeon® Processors (Contd.)

Register Address		Register Name Fields and Flags	Model Avail-ability	Shared/ Unique[1]	Bit Description
Hex	Dec				
2CH	44	MSR_EBC_FREQUENCY_ID	2,3, 4, 6	Shared	**Processor Frequency Configuration** The bit field layout of this MSR varies according to the MODEL value in the CPUID version information. The following bit field layout applies to Pentium 4 and Xeon Processors with MODEL encoding equal or greater than 2. (R) The field Indicates the current processor frequency configuration.
		15:0			Reserved.
		18:16			**Scalable Bus Speed (R/W)** Indicates the intended scalable bus speed: Encoding Scalable Bus Speed 000B 100 MHz (Model 2) 000B 266 MHz (Model 3 or 4) 001B 133 MHz 010B 200 MHz 011B 166 MHz 100B 333 MHz (Model 6)
					133.33 MHz should be utilized if performing calculation with System Bus Speed when encoding is 001B. 166.67 MHz should be utilized if performing calculation with System Bus Speed when encoding is 011B.
					266.67 MHz should be utilized if performing calculation with System Bus Speed when encoding is 000B and model encoding = 3 or 4. 333.33 MHz should be utilized if performing calculation with System Bus Speed when encoding is 100B and model encoding = 6. All other values are reserved.
		23:19			Reserved.
		31:24			**Core Clock Frequency to System Bus Frequency Ratio (R)** The processor core clock frequency to system bus frequency ratio observed at the de-assertion of the reset pin.
		63:25			Reserved.
2CH	44	MSR_EBC_FREQUENCY_ID	0, 1	Shared	**Processor Frequency Configuration (R)** The bit field layout of this MSR varies according to the MODEL value of the CPUID version information. This bit field layout applies to Pentium 4 and Xeon Processors with MODEL encoding less than 2. Indicates current processor frequency configuration.

Table 35-34. MSRs in the Pentium® 4 and Intel® Xeon® Processors (Contd.)

Register Address		Register Name Fields and Flags	Model Avail-ability	Shared/ Unique[1]	Bit Description
Hex	Dec				
		20:0			Reserved.
		23:21			**Scalable Bus Speed (R/W)** Indicates the intended scalable bus speed: Encoding Scalable Bus Speed 000B 100 MHz All others values reserved.
		63:24			Reserved.
3AH	58	IA32_FEATURE_CONTROL	3, 4, 6	Unique	**Control Features in IA-32 Processor (R/W)** See Table 35-2 (If CPUID.01H:ECX.[bit 5])
79H	121	IA32_BIOS_UPDT_TRIG	0, 1, 2, 3, 4, 6	Shared	**BIOS Update Trigger Register (W)** See Table 35-2.
8BH	139	IA32_BIOS_SIGN_ID	0, 1, 2, 3, 4, 6	Unique	**BIOS Update Signature ID (R/W)** See Table 35-2.
9BH	155	IA32_SMM_MONITOR_CTL	3, 4, 6	Unique	**SMM Monitor Configuration (R/W)** See Table 35-2.
FEH	254	IA32_MTRRCAP	0, 1, 2, 3, 4, 6	Unique	**MTRR Information** See Section 11.11.1, "MTRR Feature Identification.".
174H	372	IA32_SYSENTER_CS	0, 1, 2, 3, 4, 6	Unique	**CS register target for CPL 0 code (R/W)** See Table 35-2. See Section 5.8.7, "Performing Fast Calls to System Procedures with the SYSENTER and SYSEXIT Instructions."
175H	373	IA32_SYSENTER_ESP	0, 1, 2, 3, 4, 6	Unique	**Stack pointer for CPL 0 stack (R/W)** See Table 35-2. See Section 5.8.7, "Performing Fast Calls to System Procedures with the SYSENTER and SYSEXIT Instructions."
176H	374	IA32_SYSENTER_EIP	0, 1, 2, 3, 4, 6	Unique	**CPL 0 code entry point (R/W)** See Table 35-2. See Section 5.8.7, "Performing Fast Calls to System Procedures with the SYSENTER and SYSEXIT Instructions."
179H	377	IA32_MCG_CAP	0, 1, 2, 3, 4, 6	Unique	**Machine Check Capabilities (R)** See Table 35-2. See Section 15.3.1.1, "IA32_MCG_CAP MSR."
17AH	378	IA32_MCG_STATUS	0, 1, 2, 3, 4, 6	Unique	**Machine Check Status. (R)** See Table 35-2. See Section 15.3.1.2, "IA32_MCG_STATUS MSR."
17BH	379	IA32_MCG_CTL			**Machine Check Feature Enable (R/W)** See Table 35-2. See Section 15.3.1.3, "IA32_MCG_CTL MSR."

Table 35-34. MSRs in the Pentium® 4 and Intel® Xeon® Processors (Contd.)

Register Address		Register Name Fields and Flags	Model Avail-ability	Shared/ Unique[1]	Bit Description
Hex	Dec				
180H	384	MSR_MCG_RAX	0, 1, 2, 3, 4, 6	Unique	**Machine Check EAX/RAX Save State** See Section 15.3.2.6, "IA32_MCG Extended Machine Check State MSRs."
		63:0			Contains register state at time of machine check error. When in non-64-bit modes at the time of the error, bits 63-32 do not contain valid data.
181H	385	MSR_MCG_RBX	0, 1, 2, 3, 4, 6	Unique	**Machine Check EBX/RBX Save State** See Section 15.3.2.6, "IA32_MCG Extended Machine Check State MSRs."
		63:0			Contains register state at time of machine check error. When in non-64-bit modes at the time of the error, bits 63-32 do not contain valid data.
182H	386	MSR_MCG_RCX	0, 1, 2, 3, 4, 6	Unique	**Machine Check ECX/RCX Save State** See Section 15.3.2.6, "IA32_MCG Extended Machine Check State MSRs."
		63:0			Contains register state at time of machine check error. When in non-64-bit modes at the time of the error, bits 63-32 do not contain valid data.
183H	387	MSR_MCG_RDX	0, 1, 2, 3, 4, 6	Unique	**Machine Check EDX/RDX Save State** See Section 15.3.2.6, "IA32_MCG Extended Machine Check State MSRs."
		63:0			Contains register state at time of machine check error. When in non-64-bit modes at the time of the error, bits 63-32 do not contain valid data.
184H	388	MSR_MCG_RSI	0, 1, 2, 3, 4, 6	Unique	**Machine Check ESI/RSI Save State** See Section 15.3.2.6, "IA32_MCG Extended Machine Check State MSRs."
		63:0			Contains register state at time of machine check error. When in non-64-bit modes at the time of the error, bits 63-32 do not contain valid data.
185H	389	MSR_MCG_RDI	0, 1, 2, 3, 4, 6	Unique	**Machine Check EDI/RDI Save State** See Section 15.3.2.6, "IA32_MCG Extended Machine Check State MSRs."
		63:0			Contains register state at time of machine check error. When in non-64-bit modes at the time of the error, bits 63-32 do not contain valid data.
186H	390	MSR_MCG_RBP	0, 1, 2, 3, 4, 6	Unique	**Machine Check EBP/RBP Save State** See Section 15.3.2.6, "IA32_MCG Extended Machine Check State MSRs."
		63:0			Contains register state at time of machine check error. When in non-64-bit modes at the time of the error, bits 63-32 do not contain valid data.
187H	391	MSR_MCG_RSP	0, 1, 2, 3, 4, 6	Unique	**Machine Check ESP/RSP Save State** See Section 15.3.2.6, "IA32_MCG Extended Machine Check State MSRs."

Table 35-34. MSRs in the Pentium® 4 and Intel® Xeon® Processors (Contd.)

Register Address		Register Name Fields and Flags	Model Avail-ability	Shared/ Unique[1]	Bit Description
Hex	Dec				
		63:0			Contains register state at time of machine check error. When in non-64-bit modes at the time of the error, bits 63-32 do not contain valid data.
188H	392	MSR_MCG_RFLAGS	0, 1, 2, 3, 4, 6	Unique	**Machine Check EFLAGS/RFLAG Save State** See Section 15.3.2.6, "IA32_MCG Extended Machine Check State MSRs."
		63:0			Contains register state at time of machine check error. When in non-64-bit modes at the time of the error, bits 63-32 do not contain valid data.
189H	393	MSR_MCG_RIP	0, 1, 2, 3, 4, 6	Unique	**Machine Check EIP/RIP Save State** See Section 15.3.2.6, "IA32_MCG Extended Machine Check State MSRs."
		63:0			Contains register state at time of machine check error. When in non-64-bit modes at the time of the error, bits 63-32 do not contain valid data.
18AH	394	MSR_MCG_MISC	0, 1, 2, 3, 4, 6	Unique	**Machine Check Miscellaneous** See Section 15.3.2.6, "IA32_MCG Extended Machine Check State MSRs."
		0			**DS** When set, the bit indicates that a page assist or page fault occurred during DS normal operation. The processors response is to shut down. The bit is used as an aid for debugging DS handling code. It is the responsibility of the user (BIOS or operating system) to clear this bit for normal operation.
		63:1			Reserved.
18BH-18FH	395	MSR_MCG_RESERVED1 - MSR_MCG_RESERVED5			Reserved.
190H	400	MSR_MCG_R8	0, 1, 2, 3, 4, 6	Unique	**Machine Check R8** See Section 15.3.2.6, "IA32_MCG Extended Machine Check State MSRs."
		63:0			Registers R8-15 (and the associated state-save MSRs) exist only in Intel 64 processors. These registers contain valid information only when the processor is operating in 64-bit mode at the time of the error.
191H	401	MSR_MCG_R9	0, 1, 2, 3, 4, 6	Unique	**Machine Check R9D/R9** See Section 15.3.2.6, "IA32_MCG Extended Machine Check State MSRs."
		63:0			Registers R8-15 (and the associated state-save MSRs) exist only in Intel 64 processors. These registers contain valid information only when the processor is operating in 64-bit mode at the time of the error.

Table 35-34. MSRs in the Pentium® 4 and Intel® Xeon® Processors (Contd.)

Register Address		Register Name Fields and Flags	Model Avail-ability	Shared/ Unique[1]	Bit Description
Hex	Dec				
192H	402	MSR_MCG_R10	0, 1, 2, 3, 4, 6	Unique	**Machine Check R10** See Section 15.3.2.6, "IA32_MCG Extended Machine Check State MSRs."
		63:0			Registers R8-15 (and the associated state-save MSRs) exist only in Intel 64 processors. These registers contain valid information only when the processor is operating in 64-bit mode at the time of the error.
193H	403	MSR_MCG_R11	0, 1, 2, 3, 4, 6	Unique	**Machine Check R11** See Section 15.3.2.6, "IA32_MCG Extended Machine Check State MSRs."
		63:0			Registers R8-15 (and the associated state-save MSRs) exist only in Intel 64 processors. These registers contain valid information only when the processor is operating in 64-bit mode at the time of the error.
194H	404	MSR_MCG_R12	0, 1, 2, 3, 4, 6	Unique	**Machine Check R12** See Section 15.3.2.6, "IA32_MCG Extended Machine Check State MSRs."
		63:0			Registers R8-15 (and the associated state-save MSRs) exist only in Intel 64 processors. These registers contain valid information only when the processor is operating in 64-bit mode at the time of the error.
195H	405	MSR_MCG_R13	0, 1, 2, 3, 4, 6	Unique	**Machine Check R13** See Section 15.3.2.6, "IA32_MCG Extended Machine Check State MSRs."
		63:0			Registers R8-15 (and the associated state-save MSRs) exist only in Intel 64 processors. These registers contain valid information only when the processor is operating in 64-bit mode at the time of the error.
196H	406	MSR_MCG_R14	0, 1, 2, 3, 4, 6	Unique	**Machine Check R14** See Section 15.3.2.6, "IA32_MCG Extended Machine Check State MSRs."
		63:0			Registers R8-15 (and the associated state-save MSRs) exist only in Intel 64 processors. These registers contain valid information only when the processor is operating in 64-bit mode at the time of the error.
197H	407	MSR_MCG_R15	0, 1, 2, 3, 4, 6	Unique	**Machine Check R15** See Section 15.3.2.6, "IA32_MCG Extended Machine Check State MSRs."

Table 35-34. MSRs in the Pentium® 4 and Intel® Xeon® Processors (Contd.)

Register Address		Register Name Fields and Flags	Model Avail-ability	Shared/ Unique[1]	Bit Description
Hex	Dec				
		63:0			Registers R8-15 (and the associated state-save MSRs) exist only in Intel 64 processors. These registers contain valid information only when the processor is operating in 64-bit mode at the time of the error.
198H	408	IA32_PERF_STATUS	3, 4, 6	Unique	See Table 35-2. See Section 14.1, "Enhanced Intel Speedstep® Technology."
199H	409	IA32_PERF_CTL	3, 4, 6	Unique	See Table 35-2. See Section 14.1, "Enhanced Intel Speedstep® Technology."
19AH	410	IA32_CLOCK_MODULATION	0, 1, 2, 3, 4, 6	Unique	**Thermal Monitor Control (R/W)** See Table 35-2. See Section 14.7.3, "Software Controlled Clock Modulation."
19BH	411	IA32_THERM_INTERRUPT	0, 1, 2, 3, 4, 6	Unique	**Thermal Interrupt Control (R/W)** See Section 14.7.2, "Thermal Monitor," and see Table 35-2.
19CH	412	IA32_THERM_STATUS	0, 1, 2, 3, 4, 6	Shared	**Thermal Monitor Status (R/W)** See Section 14.7.2, "Thermal Monitor," and see Table 35-2.
19DH	413	MSR_THERM2_CTL			Thermal Monitor 2 Control.
			3,	Shared	For Family F, Model 3 processors: When read, specifies the value of the target TM2 transition last written. When set, it sets the next target value for TM2 transition.
			4, 6	Shared	For Family F, Model 4 and Model 6 processors: When read, specifies the value of the target TM2 transition last written. Writes may cause #GP exceptions.
1A0H	416	IA32_MISC_ENABLE	0, 1, 2, 3, 4, 6	Shared	**Enable Miscellaneous Processor Features (R/W)**
		0			Fast-Strings Enable. See Table 35-2.
		1			Reserved.
		2			**x87 FPU Fopcode Compatibility Mode Enable**
		3			**Thermal Monitor 1 Enable** See Section 14.7.2, "Thermal Monitor," and see Table 35-2.
		4			**Split-Lock Disable** When set, the bit causes an #AC exception to be issued instead of a split-lock cycle. Operating systems that set this bit must align system structures to avoid split-lock scenarios. When the bit is clear (default), normal split-locks are issued to the bus.

Table 35-34. MSRs in the Pentium® 4 and Intel® Xeon® Processors (Contd.)

Register Address		Register Name Fields and Flags	Model Avail-ability	Shared/ Unique[1]	Bit Description
Hex	Dec				
					This debug feature is specific to the Pentium 4 processor.
		5			Reserved.
		6			**Third-Level Cache Disable (R/W)** When set, the third-level cache is disabled; when clear (default) the third-level cache is enabled. This flag is reserved for processors that do not have a third-level cache. Note that the bit controls only the third-level cache; and only if overall caching is enabled through the CD flag of control register CR0, the page-level cache controls, and/or the MTRRs. See Section 11.5.4, "Disabling and Enabling the L3 Cache."
		7			**Performance Monitoring Available (R)** See Table 35-2.
		8			**Suppress Lock Enable** When set, assertion of LOCK on the bus is suppressed during a Split Lock access. When clear (default), LOCK is not suppressed.
		9			**Prefetch Queue Disable** When set, disables the prefetch queue. When clear (default), enables the prefetch queue.
		10			**FERR# Interrupt Reporting Enable (R/W)** When set, interrupt reporting through the FERR# pin is enabled; when clear, this interrupt reporting function is disabled.
					When this flag is set and the processor is in the stop-clock state (STPCLK# is asserted), asserting the FERR# pin signals to the processor that an interrupt (such as, INIT#, BINIT#, INTR, NMI, SMI#, or RESET#) is pending and that the processor should return to normal operation to handle the interrupt. This flag does not affect the normal operation of the FERR# pin (to indicate an unmasked floating-point error) when the STPCLK# pin is not asserted.
		11			**Branch Trace Storage Unavailable (BTS_UNAVILABLE) (R)** See Table 35-2. When set, the processor does not support branch trace storage (BTS); when clear, BTS is supported.

Table 35-34. MSRs in the Pentium® 4 and Intel® Xeon® Processors (Contd.)

Register Address		Register Name Fields and Flags	Model Avail-ability	Shared/ Unique[1]	Bit Description
Hex	Dec				
		12			**PEBS_UNAVILABLE: Precise Event Based Sampling Unavailable (R)** See Table 35-2. When set, the processor does not support precise event-based sampling (PEBS); when clear, PEBS is supported.
		13	3		**TM2 Enable (R/W)** When this bit is set (1) and the thermal sensor indicates that the die temperature is at the pre-determined threshold, the Thermal Monitor 2 mechanism is engaged. TM2 will reduce the bus to core ratio and voltage according to the value last written to MSR_THERM2_CTL bits 15:0. When this bit is clear (0, default), the processor does not change the VID signals or the bus to core ratio when the processor enters a thermal managed state. If the TM2 feature flag (ECX[8]) is not set to 1 after executing CPUID with EAX = 1, then this feature is not supported and BIOS must not alter the contents of this bit location. The processor is operating out of spec if both this bit and the TM1 bit are set to disabled states.
		17:14			Reserved.
		18	3, 4, 6		**ENABLE MONITOR FSM (R/W)** See Table 35-2.
		19			**Adjacent Cache Line Prefetch Disable (R/W)** When set to 1, the processor fetches the cache line of the 128-byte sector containing currently required data. When set to 0, the processor fetches both cache lines in the sector.
					Single processor platforms should not set this bit. Server platforms should set or clear this bit based on platform performance observed in validation and testing. BIOS may contain a setup option that controls the setting of this bit.
		21:20			Reserved.
		22	3, 4, 6		**Limit CPUID MAXVAL (R/W)** See Table 35-2. Setting this can cause unexpected behavior to software that depends on the availability of CPUID leaves greater than 3.
		23		Shared	**xTPR Message Disable (R/W)** See Table 35-2.

Table 35-34. MSRs in the Pentium® 4 and Intel® Xeon® Processors (Contd.)

Register Address		Register Name Fields and Flags	Model Avail-ability	Shared/ Unique[1]	Bit Description
Hex	Dec				
		24			**L1 Data Cache Context Mode (R/W)** When set, the L1 data cache is placed in shared mode; when clear (default), the cache is placed in adaptive mode. This bit is only enabled for IA-32 processors that support Intel Hyper-Threading Technology. See Section 11.5.6, "L1 Data Cache Context Mode." When L1 is running in adaptive mode and CR3s are identical, data in L1 is shared across logical processors. Otherwise, L1 is not shared and cache use is competitive. If the Context ID feature flag (ECX[10]) is set to 0 after executing CPUID with EAX = 1, the ability to switch modes is not supported. BIOS must not alter the contents of IA32_MISC_ENABLE[24].
		33:25			Reserved.
		34		Unique	**XD Bit Disable (R/W)** See Table 35-2.
		63:35			Reserved.
1A1H	417	MSR_PLATFORM_BRV	3, 4, 6	Shared	**Platform Feature Requirements (R)**
		17:0			Reserved.
		18			**PLATFORM Requirements** When set to 1, indicates the processor has specific platform requirements. The details of the platform requirements are listed in the respective data sheets of the processor.
		63:19			Reserved.
1D7H	471	MSR_LER_FROM_LIP	0, 1, 2, 3, 4, 6	Unique	**Last Exception Record From Linear IP (R)** Contains a pointer to the last branch instruction that the processor executed prior to the last exception that was generated or the last interrupt that was handled. See Section 17.10.3, "Last Exception Records."
		31:0			**From Linear IP** Linear address of the last branch instruction.
		63:32			Reserved.
1D7H	471	63:0		Unique	**From Linear IP** Linear address of the last branch instruction (If IA-32e mode is active).
1D8H	472	MSR_LER_TO_LIP	0, 1, 2, 3, 4, 6	Unique	**Last Exception Record To Linear IP (R)** This area contains a pointer to the target of the last branch instruction that the processor executed prior to the last exception that was generated or the last interrupt that was handled. See Section 17.10.3, "Last Exception Records."

Table 35-34. MSRs in the Pentium® 4 and Intel® Xeon® Processors (Contd.)

Register Address		Register Name Fields and Flags	Model Avail-ability	Shared/ Unique[1]	Bit Description
Hex	Dec				
		31:0			**From Linear IP** Linear address of the target of the last branch instruction.
		63:32			Reserved.
1D8H	472	63:0		Unique	**From Linear IP** Linear address of the target of the last branch instruction (If IA-32e mode is active).
1D9H	473	MSR_DEBUGCTLA	0, 1, 2, 3, 4, 6	Unique	**Debug Control (R/W)** Controls how several debug features are used. Bit definitions are discussed in the referenced section. See Section 17.10.1, "MSR_DEBUGCTLA MSR."
1DAH	474	MSR_LASTBRANCH _TOS	0, 1, 2, 3, 4, 6	Unique	**Last Branch Record Stack TOS (R/W)** Contains an index (0-3 or 0-15) that points to the top of the last branch record stack (that is, that points the index of the MSR containing the most recent branch record). See Section 17.10.2, "LBR Stack for Processors Based on Intel NetBurst® Microarchitecture"; and addresses 1DBH-1DEH and 680H-68FH.
1DBH	475	MSR_LASTBRANCH_0	0, 1, 2	Unique	**Last Branch Record 0 (R/W)** One of four last branch record registers on the last branch record stack. It contains pointers to the source and destination instruction for one of the last four branches, exceptions, or interrupts that the processor took. MSR_LASTBRANCH_0 through MSR_LASTBRANCH_3 at 1DBH-1DEH are available only on family 0FH, models 0H-02H. They have been replaced by the MSRs at 680H-68FH and 6C0H-6CFH.
					See Section 17.9, "Last Branch, Call Stack, Interrupt, and Exception Recording for Processors based on Skylake Microarchitecture."
1DDH	477	MSR_LASTBRANCH_2	0, 1, 2	Unique	**Last Branch Record 2** See description of the MSR_LASTBRANCH_0 MSR at 1DBH.
1DEH	478	MSR_LASTBRANCH_3	0, 1, 2	Unique	**Last Branch Record 3** See description of the MSR_LASTBRANCH_0 MSR at 1DBH.
200H	512	IA32_MTRR_PHYSBASE0	0, 1, 2, 3, 4, 6	Shared	**Variable Range Base MTRR** See Section 11.11.2.3, "Variable Range MTRRs."
201H	513	IA32_MTRR_PHYSMASK0	0, 1, 2, 3, 4, 6	Shared	**Variable Range Mask MTRR** See Section 11.11.2.3, "Variable Range MTRRs."

369H	873	MSR_FLAME_CCCR1	0, 1, 2, 3, 4, 6	Shared	See Section 18.13.3, "CCCR MSRs."
36AH	874	MSR_FLAME_CCCR2	0, 1, 2, 3, 4, 6	Shared	See Section 18.13.3, "CCCR MSRs."
36BH	875	MSR_FLAME_CCCR3	0, 1, 2, 3, 4, 6	Shared	See Section 18.13.3, "CCCR MSRs."
36CH	876	MSR_IQ_CCCR0	0, 1, 2, 3, 4, 6	Shared	See Section 18.13.3, "CCCR MSRs."
36DH	877	MSR_IQ_CCCR1	0, 1, 2, 3, 4, 6	Shared	See Section 18.13.3, "CCCR MSRs."
36EH	878	MSR_IQ_CCCR2	0, 1, 2, 3, 4, 6	Shared	See Section 18.13.3, "CCCR MSRs."
36FH	879	MSR_IQ_CCCR3	0, 1, 2, 3, 4, 6	Shared	See Section 18.13.3, "CCCR MSRs."

Table 35-34. MSRs in the Pentium® 4 and Intel® Xeon® Processors (Contd.)

Register Address		Register Name Fields and Flags	Model Avail-ability	Shared/ Unique[1]	Bit Description
Hex	Dec				
370H	880	MSR_IQ_CCCR4	0, 1, 2, 3, 4, 6	Shared	See Section 18.13.3, "CCCR MSRs."
371H	881	MSR_IQ_CCCR5	0, 1, 2, 3, 4, 6	Shared	See Section 18.13.3, "CCCR MSRs."
3A0H	928	MSR_BSU_ESCR0	0, 1, 2, 3, 4, 6	Shared	See Section 18.13.1, "ESCR MSRs."
3A1H	929	MSR_BSU_ESCR1	0, 1, 2, 3, 4, 6	Shared	See Section 18.13.1, "ESCR MSRs."
3A2H	930	MSR_FSB_ESCR0	0, 1, 2, 3, 4, 6	Shared	See Section 18.13.1, "ESCR MSRs."
3A3H	931	MSR_FSB_ESCR1	0, 1, 2, 3, 4, 6	Shared	See Section 18.13.1, "ESCR MSRs."
3A4H	932	MSR_FIRM_ESCR0	0, 1, 2, 3, 4, 6	Shared	See Section 18.13.1, "ESCR MSRs."
3A5H	933	MSR_FIRM_ESCR1	0, 1, 2, 3, 4, 6	Shared	See Section 18.13.1, "ESCR MSRs."
3A6H	934	MSR_FLAME_ESCR0	0, 1, 2, 3, 4, 6	Shared	See Section 18.13.1, "ESCR MSRs."
3A7H	935	MSR_FLAME_ESCR1	0, 1, 2, 3, 4, 6	Shared	See Section 18.13.1, "ESCR MSRs."
3A8H	936	MSR_DAC_ESCR0	0, 1, 2, 3, 4, 6	Shared	See Section 18.13.1, "ESCR MSRs."
3A9H	937	MSR_DAC_ESCR1	0, 1, 2, 3, 4, 6	Shared	See Section 18.13.1, "ESCR MSRs."
3AAH	938	MSR_MOB_ESCR0	0, 1, 2, 3, 4, 6	Shared	See Section 18.13.1, "ESCR MSRs."
3ABH	939	MSR_MOB_ESCR1	0, 1, 2, 3, 4, 6	Shared	See Section 18.13.1, "ESCR MSRs."
3ACH	940	MSR_PMH_ESCR0	0, 1, 2, 3, 4, 6	Shared	See Section 18.13.1, "ESCR MSRs."
3ADH	941	MSR_PMH_ESCR1	0, 1, 2, 3, 4, 6	Shared	See Section 18.13.1, "ESCR MSRs."
3AEH	942	MSR_SAAT_ESCR0	0, 1, 2, 3, 4, 6	Shared	See Section 18.13.1, "ESCR MSRs."
3AFH	943	MSR_SAAT_ESCR1	0, 1, 2, 3, 4, 6	Shared	See Section 18.13.1, "ESCR MSRs."
3B0H	944	MSR_U2L_ESCR0	0, 1, 2, 3, 4, 6	Shared	See Section 18.13.1, "ESCR MSRs."
3B1H	945	MSR_U2L_ESCR1	0, 1, 2, 3, 4, 6	Shared	See Section 18.13.1, "ESCR MSRs."
3B2H	946	MSR_BPU_ESCR0	0, 1, 2, 3, 4, 6	Shared	See Section 18.13.1, "ESCR MSRs."
3B3H	947	MSR_BPU_ESCR1	0, 1, 2, 3, 4, 6	Shared	See Section 18.13.1, "ESCR MSRs."

Table 35-34. MSRs in the Pentium® 4 and Intel® Xeon® Processors (Contd.)

Register Address		Register Name Fields and Flags	Model Avail-ability	Shared/ Unique[1]	Bit Description
Hex	Dec				
3B4H	948	MSR_IS_ESCR0	0, 1, 2, 3, 4, 6	Shared	See Section 18.13.1, "ESCR MSRs."
3B5H	949	MSR_IS_ESCR1	0, 1, 2, 3, 4, 6	Shared	See Section 18.13.1, "ESCR MSRs."
3B6H	950	MSR_ITLB_ESCR0	0, 1, 2, 3, 4, 6	Shared	See Section 18.13.1, "ESCR MSRs."
3B7H	951	MSR_ITLB_ESCR1	0, 1, 2, 3, 4, 6	Shared	See Section 18.13.1, "ESCR MSRs."
3B8H	952	MSR_CRU_ESCR0	0, 1, 2, 3, 4, 6	Shared	See Section 18.13.1, "ESCR MSRs."
3B9H	953	MSR_CRU_ESCR1	0, 1, 2, 3, 4, 6	Shared	See Section 18.13.1, "ESCR MSRs."
3BAH	954	MSR_IQ_ESCR0	0, 1, 2	Shared	See Section 18.13.1, "ESCR MSRs." This MSR is not available on later processors. It is only available on processor family 0FH, models 01H-02H.
3BBH	955	MSR_IQ_ESCR1	0, 1, 2	Shared	See Section 18.13.1, "ESCR MSRs." This MSR is not available on later processors. It is only available on processor family 0FH, models 01H-02H.
3BCH	956	MSR_RAT_ESCR0	0, 1, 2, 3, 4, 6	Shared	See Section 18.13.1, "ESCR MSRs."
3BDH	957	MSR_RAT_ESCR1	0, 1, 2, 3, 4, 6	Shared	See Section 18.13.1, "ESCR MSRs."
3BEH	958	MSR_SSU_ESCR0	0, 1, 2, 3, 4, 6	Shared	See Section 18.13.1, "ESCR MSRs."
3C0H	960	MSR_MS_ESCR0	0, 1, 2, 3, 4, 6	Shared	See Section 18.13.1, "ESCR MSRs."
3C1H	961	MSR_MS_ESCR1	0, 1, 2, 3, 4, 6	Shared	See Section 18.13.1, "ESCR MSRs."
3C2H	962	MSR_TBPU_ESCR0	0, 1, 2, 3, 4, 6	Shared	See Section 18.13.1, "ESCR MSRs."
3C3H	963	MSR_TBPU_ESCR1	0, 1, 2, 3, 4, 6	Shared	See Section 18.13.1, "ESCR MSRs."
3C4H	964	MSR_TC_ESCR0	0, 1, 2, 3, 4, 6	Shared	See Section 18.13.1, "ESCR MSRs."
3C5H	965	MSR_TC_ESCR1	0, 1, 2, 3, 4, 6	Shared	See Section 18.13.1, "ESCR MSRs."
3C8H	968	MSR_IX_ESCR0	0, 1, 2, 3, 4, 6	Shared	See Section 18.13.1, "ESCR MSRs."
3C9H	969	MSR_IX_ESCR1	0, 1, 2, 3, 4, 6	Shared	See Section 18.13.1, "ESCR MSRs."
3CAH	970	MSR_ALF_ESCR0	0, 1, 2, 3, 4, 6	Shared	See Section 18.13.1, "ESCR MSRs."

Table 35-34. MSRs in the Pentium® 4 and Intel® Xeon® Processors (Contd.)

Register Address		Register Name Fields and Flags	Model Avail-ability	Shared/ Unique[1]	Bit Description
Hex	Dec				
3CBH	971	MSR_ALF_ESCR1	0, 1, 2, 3, 4, 6	Shared	See Section 18.13.1, "ESCR MSRs."
3CCH	972	MSR_CRU_ESCR2	0, 1, 2, 3, 4, 6	Shared	See Section 18.13.1, "ESCR MSRs."
3CDH	973	MSR_CRU_ESCR3	0, 1, 2, 3, 4, 6	Shared	See Section 18.13.1, "ESCR MSRs."
3E0H	992	MSR_CRU_ESCR4	0, 1, 2, 3, 4, 6	Shared	See Section 18.13.1, "ESCR MSRs."
3E1H	993	MSR_CRU_ESCR5	0, 1, 2, 3, 4, 6	Shared	See Section 18.13.1, "ESCR MSRs."
3F0H	1008	MSR_TC_PRECISE_EVENT	0, 1, 2, 3, 4, 6	Shared	See Section 18.13.1, "ESCR MSRs."
3F1H	1009	MSR_PEBS_ENABLE	0, 1, 2, 3, 4, 6	Shared	**Precise Event-Based Sampling (PEBS) (R/W)** Controls the enabling of precise event sampling and replay tagging.
		12:0			See Table 19-32.
		23:13			Reserved.
		24			**UOP Tag** Enables replay tagging when set.
		25			**ENABLE_PEBS_MY_THR (R/W)** Enables PEBS for the target logical processor when set; disables PEBS when clear (default). See Section 18.14.3, "IA32_PEBS_ENABLE MSR," for an explanation of the target logical processor. This bit is called ENABLE_PEBS in IA-32 processors that do not support Intel Hyper-Threading Technology.
		26			**ENABLE_PEBS_OTH_THR (R/W)** Enables PEBS for the target logical processor when set; disables PEBS when clear (default). See Section 18.14.3, "IA32_PEBS_ENABLE MSR," for an explanation of the target logical processor. This bit is reserved for IA-32 processors that do not support Intel Hyper-Threading Technology.
		63:27			Reserved.
3F2H	1010	MSR_PEBS_MATRIX_VERT	0, 1, 2, 3, 4, 6	Shared	See Table 19-32.
400H	1024	IA32_MC0_CTL	0, 1, 2, 3, 4, 6	Shared	See Section 15.3.2.1, "IA32_MCi_CTL MSRs."
401H	1025	IA32_MC0_STATUS	0, 1, 2, 3, 4, 6	Shared	See Section 15.3.2.2, "IA32_MCi_STATUS MSRS."

Table 35-34. MSRs in the Pentium® 4 and Intel® Xeon® Processors (Contd.)

Register Address		Register Name Fields and Flags	Model Avail-ability	Shared/ Unique[1]	Bit Description
Hex	Dec				
402H	1026	IA32_MC0_ADDR	0, 1, 2, 3, 4, 6	Shared	See Section 15.3.2.3, "IA32_MCi_ADDR MSRs." The IA32_MC0_ADDR register is either not implemented or contains no address if the ADDRV flag in the IA32_MC0_STATUS register is clear. When not implemented in the processor, all reads and writes to this MSR will cause a general-protection exception.
403H	1027	IA32_MC0_MISC	0, 1, 2, 3, 4, 6	Shared	See Section 15.3.2.4, "IA32_MCi_MISC MSRs." The IA32_MC0_MISC MSR is either not implemented or does not contain additional information if the MISCV flag in the IA32_MC0_STATUS register is clear. When not implemented in the processor, all reads and writes to this MSR will cause a general-protection exception.
404H	1028	IA32_MC1_CTL	0, 1, 2, 3, 4, 6	Shared	See Section 15.3.2.1, "IA32_MCi_CTL MSRs."
405H	1029	IA32_MC1_STATUS	0, 1, 2, 3, 4, 6	Shared	See Section 15.3.2.2, "IA32_MCi_STATUS MSRS."
406H	1030	IA32_MC1_ADDR	0, 1, 2, 3, 4, 6	Shared	See Section 15.3.2.3, "IA32_MCi_ADDR MSRs." The IA32_MC1_ADDR register is either not implemented or contains no address if the ADDRV flag in the IA32_MC1_STATUS register is clear. When not implemented in the processor, all reads and writes to this MSR will cause a general-protection exception.
407H	1031	IA32_MC1_MISC		Shared	See Section 15.3.2.4, "IA32_MCi_MISC MSRs." The IA32_MC1_MISC MSR is either not implemented or does not contain additional information if the MISCV flag in the IA32_MC1_STATUS register is clear. When not implemented in the processor, all reads and writes to this MSR will cause a general-protection exception.
408H	1032	IA32_MC2_CTL	0, 1, 2, 3, 4, 6	Shared	See Section 15.3.2.1, "IA32_MCi_CTL MSRs."
409H	1033	IA32_MC2_STATUS	0, 1, 2, 3, 4, 6	Shared	See Section 15.3.2.2, "IA32_MCi_STATUS MSRS."
40AH	1034	IA32_MC2_ADDR			See Section 15.3.2.3, "IA32_MCi_ADDR MSRs." The IA32_MC2_ADDR register is either not implemented or contains no address if the ADDRV flag in the IA32_MC2_STATUS register is clear. When not implemented in the processor, all reads and writes to this MSR will cause a general-protection exception.

Table 35-34. MSRs in the Pentium® 4 and Intel® Xeon® Processors (Contd.)

Register Address		Register Name Fields and Flags	Model Avail-ability	Shared/ Unique[1]	Bit Description
Hex	Dec				
40BH	1035	IA32_MC2_MISC			See Section 15.3.2.4, "IA32_MCi_MISC MSRs." The IA32_MC2_MISC MSR is either not implemented or does not contain additional information if the MISCV flag in the IA32_MC2_STATUS register is clear. When not implemented in the processor, all reads and writes to this MSR will cause a general-protection exception.
40CH	1036	IA32_MC3_CTL	0, 1, 2, 3, 4, 6	Shared	See Section 15.3.2.1, "IA32_MCi_CTL MSRs."
40DH	1037	IA32_MC3_STATUS	0, 1, 2, 3, 4, 6	Shared	See Section 15.3.2.2, "IA32_MCi_STATUS MSRS."
40EH	1038	IA32_MC3_ADDR	0, 1, 2, 3, 4, 6	Shared	See Section 15.3.2.3, "IA32_MCi_ADDR MSRs." The IA32_MC3_ADDR register is either not implemented or contains no address if the ADDRV flag in the IA32_MC3_STATUS register is clear. When not implemented in the processor, all reads and writes to this MSR will cause a general-protection exception.
40FH	1039	IA32_MC3_MISC	0, 1, 2, 3, 4, 6	Shared	See Section 15.3.2.4, "IA32_MCi_MISC MSRs." The IA32_MC3_MISC MSR is either not implemented or does not contain additional information if the MISCV flag in the IA32_MC3_STATUS register is clear. When not implemented in the processor, all reads and writes to this MSR will cause a general-protection exception.
410H	1040	IA32_MC4_CTL	0, 1, 2, 3, 4, 6	Shared	See Section 15.3.2.1, "IA32_MCi_CTL MSRs."
411H	1041	IA32_MC4_STATUS	0, 1, 2, 3, 4, 6	Shared	See Section 15.3.2.2, "IA32_MCi_STATUS MSRS."
412H	1042	IA32_MC4_ADDR			See Section 15.3.2.3, "IA32_MCi_ADDR MSRs." The IA32_MC2_ADDR register is either not implemented or contains no address if the ADDRV flag in the IA32_MC4_STATUS register is clear. When not implemented in the processor, all reads and writes to this MSR will cause a general-protection exception.
413H	1043	IA32_MC4_MISC			See Section 15.3.2.4, "IA32_MCi_MISC MSRs." The IA32_MC2_MISC MSR is either not implemented or does not contain additional information if the MISCV flag in the IA32_MC4_STATUS register is clear. When not implemented in the processor, all reads and writes to this MSR will cause a general-protection exception.

Table 35-34. MSRs in the Pentium® 4 and Intel® Xeon® Processors (Contd.)

Register Address		Register Name Fields and Flags	Model Avail-ability	Shared/ Unique[1]	Bit Description
Hex	Dec				
480H	1152	IA32_VMX_BASIC	3, 4, 6	Unique	**Reporting Register of Basic VMX Capabilities (R/O)** See Table 35-2. See Appendix A.1, "Basic VMX Information."
481H	1153	IA32_VMX_PINBASED_CTLS	3, 4, 6	Unique	**Capability Reporting Register of Pin-based VM-execution Controls (R/O)** See Table 35-2. See Appendix A.3, "VM-Execution Controls."
482H	1154	IA32_VMX_PROCBASED_CTLS	3, 4, 6	Unique	**Capability Reporting Register of Primary Processor-based VM-execution Controls (R/O)** See Appendix A.3, "VM-Execution Controls," and see Table 35-2.
483H	1155	IA32_VMX_EXIT_CTLS	3, 4, 6	Unique	**Capability Reporting Register of VM-exit Controls (R/O)** See Appendix A.4, "VM-Exit Controls," and see Table 35-2.
484H	1156	IA32_VMX_ENTRY_CTLS	3, 4, 6	Unique	**Capability Reporting Register of VM-entry Controls (R/O)** See Appendix A.5, "VM-Entry Controls," and see Table 35-2.
485H	1157	IA32_VMX_MISC	3, 4, 6	Unique	**Reporting Register of Miscellaneous VMX Capabilities (R/O)** See Appendix A.6, "Miscellaneous Data," and see Table 35-2.
486H	1158	IA32_VMX_CR0_FIXED0	3, 4, 6	Unique	**Capability Reporting Register of CR0 Bits Fixed to 0 (R/O)** See Appendix A.7, "VMX-Fixed Bits in CR0," and see Table 35-2.
487H	1159	IA32_VMX_CR0_FIXED1	3, 4, 6	Unique	**Capability Reporting Register of CR0 Bits Fixed to 1 (R/O)** See Appendix A.7, "VMX-Fixed Bits in CR0," and see Table 35-2.
488H	1160	IA32_VMX_CR4_FIXED0	3, 4, 6	Unique	**Capability Reporting Register of CR4 Bits Fixed to 0 (R/O)** See Appendix A.8, "VMX-Fixed Bits in CR4," and see Table 35-2.
489H	1161	IA32_VMX_CR4_FIXED1	3, 4, 6	Unique	**Capability Reporting Register of CR4 Bits Fixed to 1 (R/O)** See Appendix A.8, "VMX-Fixed Bits in CR4," and see Table 35-2.
48AH	1162	IA32_VMX_VMCS_ENUM	3, 4, 6	Unique	**Capability Reporting Register of VMCS Field Enumeration (R/O)** See Appendix A.9, "VMCS Enumeration," and see Table 35-2.

Table 35-34. MSRs in the Pentium® 4 and Intel® Xeon® Processors (Contd.)

Register Address		Register Name Fields and Flags	Model Avail-ability	Shared/ Unique[1]	Bit Description
Hex	Dec				
48BH	1163	IA32_VMX_PROCBASED_CTLS2	3, 4, 6	Unique	**Capability Reporting Register of Secondary Processor-based VM-execution Controls (R/O)** See Appendix A.3, "VM-Execution Controls," and see Table 35-2.
600H	1536	IA32_DS_AREA	0, 1, 2, 3, 4, 6	Unique	**DS Save Area (R/W)** See Table 35-2. See Section 18.13.4, "Debug Store (DS) Mechanism."
680H	1664	MSR_LASTBRANCH_0_FROM_IP	3, 4, 6	Unique	**Last Branch Record 0 (R/W)** One of 16 pairs of last branch record registers on the last branch record stack (680H-68FH). This part of the stack contains pointers to the **source instruction** for one of the last 16 branches, exceptions, or interrupts taken by the processor.
					The MSRs at 680H-68FH, 6C0H-6CfH are not available in processor releases before family 0FH, model 03H. These MSRs replace MSRs previously located at 1DBH-1DEH.which performed the same function for early releases. See Section 17.9, "Last Branch, Call Stack, Interrupt, and Exception Recording for Processors based on Skylake Microarchitecture."
681H	1665	MSR_LASTBRANCH_1_FROM_IP	3, 4, 6	Unique	**Last Branch Record 1** See description of MSR_LASTBRANCH_0 at 680H.
682H	1666	MSR_LASTBRANCH_2_FROM_IP	3, 4, 6	Unique	**Last Branch Record 2** See description of MSR_LASTBRANCH_0 at 680H.
683H	1667	MSR_LASTBRANCH_3_FROM_IP	3, 4, 6	Unique	**Last Branch Record 3** See description of MSR_LASTBRANCH_0 at 680H.
684H	1668	MSR_LASTBRANCH_4_FROM_IP	3, 4, 6	Unique	**Last Branch Record 4** See description of MSR_LASTBRANCH_0 at 680H.
685H	1669	MSR_LASTBRANCH_5_FROM_IP	3, 4, 6	Unique	**Last Branch Record 5** See description of MSR_LASTBRANCH_0 at 680H.
686H	1670	MSR_LASTBRANCH_6_FROM_IP	3, 4, 6	Unique	**Last Branch Record 6** See description of MSR_LASTBRANCH_0 at 680H.
687H	1671	MSR_LASTBRANCH_7_FROM_IP	3, 4, 6	Unique	**Last Branch Record 7** See description of MSR_LASTBRANCH_0 at 680H.
688H	1672	MSR_LASTBRANCH_8_FROM_IP	3, 4, 6	Unique	**Last Branch Record 8** See description of MSR_LASTBRANCH_0 at 680H.
689H	1673	MSR_LASTBRANCH_9_FROM_IP	3, 4, 6	Unique	**Last Branch Record 9** See description of MSR_LASTBRANCH_0 at 680H.
68AH	1674	MSR_LASTBRANCH_10_FROM_IP	3, 4, 6	Unique	**Last Branch Record 10** See description of MSR_LASTBRANCH_0 at 680H.

Table 35-34. MSRs in the Pentium® 4 and Intel® Xeon® Processors (Contd.)

Register Address		Register Name Fields and Flags	Model Avail-ability	Shared/ Unique[1]	Bit Description
Hex	Dec				
68BH	1675	MSR_LASTBRANCH_11_FROM_IP	3, 4, 6	Unique	**Last Branch Record 11** See description of MSR_LASTBRANCH_0 at 680H.
68CH	1676	MSR_LASTBRANCH_12_FROM_IP	3, 4, 6	Unique	**Last Branch Record 12** See description of MSR_LASTBRANCH_0 at 680H.
68DH	1677	MSR_LASTBRANCH_13_FROM_IP	3, 4, 6	Unique	**Last Branch Record 13** See description of MSR_LASTBRANCH_0 at 680H.
68EH	1678	MSR_LASTBRANCH_14_FROM_IP	3, 4, 6	Unique	**Last Branch Record 14** See description of MSR_LASTBRANCH_0 at 680H.
68FH	1679	MSR_LASTBRANCH_15_FROM_IP	3, 4, 6	Unique	**Last Branch Record 15** See description of MSR_LASTBRANCH_0 at 680H.
6C0H	1728	MSR_LASTBRANCH_0_TO_IP	3, 4, 6	Unique	**Last Branch Record 0 (R/W)** One of 16 pairs of last branch record registers on the last branch record stack (6C0H-6CFH). This part of the stack contains pointers to the destination instruction for one of the last 16 branches, exceptions, or interrupts that the processor took. See Section 17.9, "Last Branch, Call Stack, Interrupt, and Exception Recording for Processors based on Skylake Microarchitecture."
6C1H	1729	MSR_LASTBRANCH_1_TO_IP	3, 4, 6	Unique	**Last Branch Record 1** See description of MSR_LASTBRANCH_0 at 6C0H.
6C2H	1730	MSR_LASTBRANCH_2_TO_IP	3, 4, 6	Unique	**Last Branch Record 2** See description of MSR_LASTBRANCH_0 at 6C0H.
6C3H	1731	MSR_LASTBRANCH_3_TO_IP	3, 4, 6	Unique	**Last Branch Record 3** See description of MSR_LASTBRANCH_0 at 6C0H.
6C4H	1732	MSR_LASTBRANCH_4_TO_IP	3, 4, 6	Unique	**Last Branch Record 4** See description of MSR_LASTBRANCH_0 at 6C0H.
6C5H	1733	MSR_LASTBRANCH_5_TO_IP	3, 4, 6	Unique	**Last Branch Record 5** See description of MSR_LASTBRANCH_0 at 6C0H.
6C6H	1734	MSR_LASTBRANCH_6_TO_IP	3, 4, 6	Unique	**Last Branch Record 6** See description of MSR_LASTBRANCH_0 at 6C0H.
6C7H	1735	MSR_LASTBRANCH_7_TO_IP	3, 4, 6	Unique	**Last Branch Record 7** See description of MSR_LASTBRANCH_0 at 6C0H.
6C8H	1736	MSR_LASTBRANCH_8_TO_IP	3, 4, 6	Unique	**Last Branch Record 8** See description of MSR_LASTBRANCH_0 at 6C0H.
6C9H	1737	MSR_LASTBRANCH_9_TO_IP	3, 4, 6	Unique	**Last Branch Record 9** See description of MSR_LASTBRANCH_0 at 6C0H.
6CAH	1738	MSR_LASTBRANCH_10_TO_IP	3, 4, 6	Unique	**Last Branch Record 10** See description of MSR_LASTBRANCH_0 at 6C0H.

6CFH	1743	MSR_LASTBRANCH_15_TO_IP	3, 4, 6	Unique	**Last Branch Record 15** See description of MSR_LASTBRANCH_0 at 6C0H.
C000_0080H		IA32_EFER	3, 4, 6	Unique	**Extended Feature Enables** See Table 35-2.
C000_0081H		IA32_STAR	3, 4, 6	Unique	**System Call Target Address (R/W)** See Table 35-2.
C000_0082H		IA32_LSTAR	3, 4, 6	Unique	**IA-32e Mode System Call Target Address (R/W)** See Table 35-2.
C000_0084H		IA32_FMASK	3, 4, 6	Unique	**System Call Flag Mask (R/W)** See Table 35-2.
C000_0100H		IA32_FS_BASE	3, 4, 6	Unique	**Map of BASE Address of FS (R/W)** See Table 35-2.
C000_0101H		IA32_GS_BASE	3, 4, 6	Unique	**Map of BASE Address of GS (R/W)** See Table 35-2.
C000_0102H		IA32_KERNEL_GSBASE	3, 4, 6	Unique	**Swap Target of BASE Address of GS (R/W)** See Table 35-2.

NOTES

1. For HT-enabled processors, there may be more than one logical processors per physical unit. If an MSR is Shared, this means that one MSR is shared between logical processors. If an MSR is unique, this means that each logical processor has its own MSR.

35.16.1 MSRs Unique to Intel® Xeon® Processor MP with L3 Cache

The MSRs listed in Table 35-35 apply to Intel® Xeon® Processor MP with up to 8MB level three cache. These processors can be detected by enumerating the deterministic cache parameter leaf of CPUID instruction (with EAX = 4 as input) to detect the presence of the third level cache, and with CPUID reporting family encoding 0FH, model encoding 3 or 4 (see CPUID instruction for more details).

Table 35-35. MSRs Unique to 64-bit Intel® Xeon® Processor MP with Up to an 8 MB L3 Cache

Register Address		Register Name Fields and Flags	Model Avail-ability	Shared/ Unique	Bit Description
107CCH		MSR_IFSB_BUSQ0	3, 4	Shared	**IFSB BUSQ Event Control and Counter Register (R/W)** See Section 18.18, "Performance Monitoring on 64-bit Intel Xeon Processor MP with Up to 8-MByte L3 Cache."
107CDH		MSR_IFSB_BUSQ1	3, 4	Shared	**IFSB BUSQ Event Control and Counter Register (R/W)**
107CEH		MSR_IFSB_SNPQ0	3, 4	Shared	**IFSB SNPQ Event Control and Counter Register (R/W)** See Section 18.18, "Performance Monitoring on 64-bit Intel Xeon Processor MP with Up to 8-MByte L3 Cache."
107CFH		MSR_IFSB_SNPQ1	3, 4	Shared	**IFSB SNPQ Event Control and Counter Register (R/W)**
107D0H		MSR_EFSB_DRDY0	3, 4	Shared	**EFSB DRDY Event Control and Counter Register (R/W)** See Section 18.18, "Performance Monitoring on 64-bit Intel Xeon Processor MP with Up to 8-MByte L3 Cache" for details.
107D1H		MSR_EFSB_DRDY1	3, 4	Shared	**EFSB DRDY Event Control and Counter Register (R/W)**
107D2H		MSR_IFSB_CTL6	3, 4	Shared	**IFSB Latency Event Control Register (R/W)** See Section 18.18, "Performance Monitoring on 64-bit Intel Xeon Processor MP with Up to 8-MByte L3 Cache" for details.
107D3H		MSR_IFSB_CNTR7	3, 4	Shared	**IFSB Latency Event Counter Register (R/W)** See Section 18.18, "Performance Monitoring on 64-bit Intel Xeon Processor MP with Up to 8-MByte L3 Cache."

The MSRs listed in Table 35-36 apply to Intel® Xeon® Processor 7100 series. These processors can be detected by enumerating the deterministic cache parameter leaf of CPUID instruction (with EAX = 4 as input) to detect the presence of the third level cache, and with CPUID reporting family encoding 0FH, model encoding 6 (See CPUID instruction for more details.). The performance monitoring MSRs listed in Table 35-36 are shared between logical processors in the same core, but are replicated for each core.

Table 35-36. MSRs Unique to Intel® Xeon® Processor 7100 Series

Register Address		Register Name Fields and Flags	Model Availability	Shared/ Unique	Bit Description
107CCH		MSR_EMON_L3_CTR_CTL0	6	Shared	**GBUSQ Event Control and Counter Register (R/W)** See Section 18.18, "Performance Monitoring on 64-bit Intel Xeon Processor MP with Up to 8-MByte L3 Cache."
107CDH		MSR_EMON_L3_CTR_CTL1	6	Shared	**GBUSQ Event Control and Counter Register (R/W)**
107CEH		MSR_EMON_L3_CTR_CTL2	6	Shared	**GSNPQ Event Control and Counter Register (R/W)** See Section 18.18, "Performance Monitoring on 64-bit Intel Xeon Processor MP with Up to 8-MByte L3 Cache."
107CFH		MSR_EMON_L3_CTR_CTL3	6	Shared	**GSNPQ Event Control and Counter Register (R/W)**
107D0H		MSR_EMON_L3_CTR_CTL4	6	Shared	**FSB Event Control and Counter Register (R/W)** See Section 18.18, "Performance Monitoring on 64-bit Intel Xeon Processor MP with Up to 8-MByte L3 Cache" for details.
107D1H		MSR_EMON_L3_CTR_CTL5	6	Shared	**FSB Event Control and Counter Register (R/W)**
107D2H		MSR_EMON_L3_CTR_CTL6	6	Shared	**FSB Event Control and Counter Register (R/W)**
107D3H		MSR_EMON_L3_CTR_CTL7	6	Shared	**FSB Event Control and Counter Register (R/W)**

35.17 MSRS IN INTEL® CORE™ SOLO AND INTEL® CORE™ DUO PROCESSORS

Model-specific registers (MSRs) for Intel Core Solo, Intel Core Duo processors, and Dual-core Intel Xeon processor LV are listed in Table 35-37. The column "Shared/Unique" applies to Intel Core Duo processor. "Unique" means each processor core has a separate MSR, or a bit field in an MSR governs only a core independently. "Shared" means the MSR or the bit field in an MSR address governs the operation of both processor cores.

Table 35-37. MSRs in Intel® Core™ Solo, Intel® Core™ Duo Processors, and Dual-Core Intel® Xeon® Processor LV

Register Address		Register Name	Shared/ Unique	Bit Description
Hex	Dec			
0H	0	P5_MC_ADDR	Unique	See Section 35.20, "MSRs in Pentium Processors," and see Table 35-2.
1H	1	P5_MC_TYPE	Unique	See Section 35.20, "MSRs in Pentium Processors," and see Table 35-2.
6H	6	IA32_MONITOR_FILTER_SIZE	Unique	See Section 8.10.5, "Monitor/Mwait Address Range Determination," and see Table 35-2.

Table 35-37. MSRs in Intel® Core™ Solo, Intel® Core™ Duo Processors, and Dual-Core Intel® Xeon® Processor LV

Register Address		Register Name	Shared/ Unique	Bit Description
Hex	Dec			
10H	16	IA32_TIME_STAMP_ COUNTER	Unique	See Section 17.14, "Time-Stamp Counter," and see Table 35-2.
17H	23	IA32_PLATFORM_ID	Shared	**Platform ID (R)** See Table 35-2. The operating system can use this MSR to determine "slot" information for the processor and the proper microcode update to load.
1BH	27	IA32_APIC_BASE	Unique	See Section 10.4.4, "Local APIC Status and Location," and see Table 35-2.
2AH	42	MSR_EBL_CR_POWERON	Shared	**Processor Hard Power-On Configuration (R/W)** Enables and disables processor features; (R) indicates current processor configuration.
		0		Reserved.
		1		**Data Error Checking Enable (R/W)** 1 = Enabled; 0 = Disabled Note: Not all processor implements R/W.
		2		**Response Error Checking Enable (R/W)** 1 = Enabled; 0 = Disabled Note: Not all processor implements R/W.
		3		**MCERR# Drive Enable (R/W)** 1 = Enabled; 0 = Disabled Note: Not all processor implements R/W.
		4		**Address Parity Enable (R/W)** 1 = Enabled; 0 = Disabled Note: Not all processor implements R/W.
		6: 5		Reserved
		7		**BINIT# Driver Enable (R/W)** 1 = Enabled; 0 = Disabled Note: Not all processor implements R/W.
		8		**Output Tri-state Enabled (R/O)** 1 = Enabled; 0 = Disabled
		9		**Execute BIST (R/O)** 1 = Enabled; 0 = Disabled
		10		**MCERR# Observation Enabled (R/O)** 1 = Enabled; 0 = Disabled
		11		Reserved
		12		**BINIT# Observation Enabled (R/O)** 1 = Enabled; 0 = Disabled
		13		Reserved
		14		**1 MByte Power on Reset Vector (R/O)** 1 = 1 MByte; 0 = 4 GBytes

Table 35-37. MSRs in Intel® Core™ Solo, Intel® Core™ Duo Processors, and Dual-Core Intel® Xeon® Processor LV

Register Address		Register Name	Shared/ Unique	Bit Description
Hex	Dec			
		15		Reserved
		17:16		**APIC Cluster ID (R/O)**
		18		**System Bus Frequency (R/O)** 0 = 100 MHz 1 = Reserved
		19		Reserved.
		21: 20		**Symmetric Arbitration ID (R/O)**
		26:22		**Clock Frequency Ratio (R/O)**
3AH	58	IA32_FEATURE_CONTROL	Unique	**Control Features in IA-32 Processor (R/W)** See Table 35-2.
40H	64	MSR_LASTBRANCH_0	Unique	**Last Branch Record 0 (R/W)** One of 8 last branch record registers on the last branch record stack: bits 31-0 hold the 'from' address and bits 63-32 hold the 'to' address. See also: ▪ Last Branch Record Stack TOS at 1C9H ▪ Section 17.12, "Last Branch, Interrupt, and Exception Recording (Pentium M Processors)."
41H	65	MSR_LASTBRANCH_1	Unique	**Last Branch Record 1 (R/W)** See description of MSR_LASTBRANCH_0.
42H	66	MSR_LASTBRANCH_2	Unique	**Last Branch Record 2 (R/W)** See description of MSR_LASTBRANCH_0.
43H	67	MSR_LASTBRANCH_3	Unique	**Last Branch Record 3 (R/W)** See description of MSR_LASTBRANCH_0.
44H	68	MSR_LASTBRANCH_4	Unique	**Last Branch Record 4 (R/W)** See description of MSR_LASTBRANCH_0.
45H	69	MSR_LASTBRANCH_5	Unique	**Last Branch Record 5 (R/W)** See description of MSR_LASTBRANCH_0.
46H	70	MSR_LASTBRANCH_6	Unique	**Last Branch Record 6 (R/W)** See description of MSR_LASTBRANCH_0.
47H	71	MSR_LASTBRANCH_7	Unique	**Last Branch Record 7 (R/W)** See description of MSR_LASTBRANCH_0.
79H	121	IA32_BIOS_UPDT_TRIG	Unique	**BIOS Update Trigger Register (W)** See Table 35-2.
8BH	139	IA32_BIOS_SIGN_ID	Unique	**BIOS Update Signature ID (RO)** See Table 35-2.
C1H	193	IA32_PMC0	Unique	**Performance counter register** See Table 35-2.
C2H	194	IA32_PMC1	Unique	**Performance counter register** See Table 35-2.

Table 35-37. MSRs in Intel® Core™ Solo, Intel® Core™ Duo Processors, and Dual-Core Intel® Xeon® Processor LV

Register Address		Register Name	Shared/ Unique	Bit Description
Hex	Dec			
CDH	205	MSR_FSB_FREQ	Shared	**Scaleable Bus Speed (RO)** This field indicates the scaleable bus clock speed:
		2:0		▪ 101B: 100 MHz (FSB 400) ▪ 001B: 133 MHz (FSB 533) ▪ 011B: 167 MHz (FSB 667) 133.33 MHz should be utilized if performing calculation with System Bus Speed when encoding is 101B. 166.67 MHz should be utilized if performing calculation with System Bus Speed when encoding is 001B.
		63:3		Reserved.
E7H	231	IA32_MPERF	Unique	**Maximum Performance Frequency Clock Count. (RW)** See Table 35-2.
E8H	232	IA32_APERF	Unique	**Actual Performance Frequency Clock Count. (RW)** See Table 35-2.
FEH	254	IA32_MTRRCAP	Unique	See Table 35-2.
11EH	281	MSR_BBL_CR_CTL3	Shared	
		0		**L2 Hardware Enabled (RO)** 1 = If the L2 is hardware-enabled 0 = Indicates if the L2 is hardware-disabled
		7:1		Reserved.
		8		**L2 Enabled (R/W)** 1 = L2 cache has been initialized 0 = Disabled (default) Until this bit is set the processor will not respond to the WBINVD instruction or the assertion of the FLUSH# input.
		22:9		Reserved.
		23		**L2 Not Present (RO)** 0 = L2 Present 1 = L2 Not Present
		63:24		Reserved.
174H	372	IA32_SYSENTER_CS	Unique	See Table 35-2.
175H	373	IA32_SYSENTER_ESP	Unique	See Table 35-2.
176H	374	IA32_SYSENTER_EIP	Unique	See Table 35-2.
179H	377	IA32_MCG_CAP	Unique	See Table 35-2.
17AH	378	IA32_MCG_STATUS	Unique	

Table 35-37. MSRs in Intel® Core™ Solo, Intel® Core™ Duo Processors, and Dual-Core Intel® Xeon® Processor LV

Register Address		Register Name	Shared/ Unique	Bit Description
Hex	Dec			
		0		**RIPV** When set, this bit indicates that the instruction addressed by the instruction pointer pushed on the stack (when the machine check was generated) can be used to restart the program. If this bit is cleared, the program cannot be reliably restarted.
		1		**EIPV** When set, this bit indicates that the instruction addressed by the instruction pointer pushed on the stack (when the machine check was generated) is directly associated with the error.
		2		**MCIP** When set, this bit indicates that a machine check has been generated. If a second machine check is detected while this bit is still set, the processor enters a shutdown state. Software should write this bit to 0 after processing a machine check exception.
		63:3		Reserved.
186H	390	IA32_PERFEVTSEL0	Unique	See Table 35-2.
187H	391	IA32_PERFEVTSEL1	Unique	See Table 35-2.
198H	408	IA32_PERF_STATUS	Shared	See Table 35-2.
199H	409	IA32_PERF_CTL	Unique	See Table 35-2.
19AH	410	IA32_CLOCK_ MODULATION	Unique	**Clock Modulation (R/W)** See Table 35-2.
19BH	411	IA32_THERM_ INTERRUPT	Unique	**Thermal Interrupt Control (R/W)** See Table 35-2. See Section 14.7.2, "Thermal Monitor."
19CH	412	IA32_THERM_STATUS	Unique	**Thermal Monitor Status (R/W)** See Table 35-2. See Section 14.7.2, "Thermal Monitor".
19DH	413	MSR_THERM2_CTL	Unique	
		15:0		Reserved.
		16		**TM_SELECT (R/W)** Mode of automatic thermal monitor: 0 = Thermal Monitor 1 (thermally-initiated on-die modulation of the stop-clock duty cycle) 1 = Thermal Monitor 2 (thermally-initiated frequency transitions) If bit 3 of the IA32_MISC_ENABLE register is cleared, TM_SELECT has no effect. Neither TM1 nor TM2 will be enabled.
		63:16		Reserved.
1A0H	416	IA32_MISC_ENABLE		**Enable Miscellaneous Processor Features (R/W)** Allows a variety of processor functions to be enabled and disabled.
		2:0		Reserved.

Table 35-37. MSRs in Intel® Core™ Solo, Intel® Core™ Duo Processors, and Dual-Core Intel® Xeon® Processor LV

Register Address		Register Name	Shared/ Unique	Bit Description
Hex	Dec			
		3	Unique	**Automatic Thermal Control Circuit Enable (R/W)** See Table 35-2.
		6:4		Reserved.
		7	Shared	**Performance Monitoring Available (R)** See Table 35-2.
		9:8		Reserved.
		10	Shared	**FERR# Multiplexing Enable (R/W)** 1 = FERR# asserted by the processor to indicate a pending break event within the processor 0 = Indicates compatible FERR# signaling behavior This bit must be set to 1 to support XAPIC interrupt model usage.
		11	Shared	**Branch Trace Storage Unavailable (RO)** See Table 35-2.
		12		Reserved.
		13	Shared	**TM2 Enable (R/W)** When this bit is set (1) and the thermal sensor indicates that the die temperature is at the pre-determined threshold, the Thermal Monitor 2 mechanism is engaged. TM2 will reduce the bus to core ratio and voltage according to the value last written to MSR_THERM2_CTL bits 15:0.
				When this bit is clear (0, default), the processor does not change the VID signals or the bus to core ratio when the processor enters a thermal managed state. If the TM2 feature flag (ECX[8]) is not set to 1 after executing CPUID with EAX = 1, then this feature is not supported and BIOS must not alter the contents of this bit location. The processor is operating out of spec if both this bit and the TM1 bit are set to disabled states.
		15:14		Reserved.
		16	Shared	**Enhanced Intel SpeedStep Technology Enable (R/W)** 1 = Enhanced Intel SpeedStep Technology enabled
		18	Shared	**ENABLE MONITOR FSM (R/W)** See Table 35-2.
		19		**Reserved.**
		22	Shared	**Limit CPUID Maxval (R/W)** See Table 35-2. Setting this bit may cause behavior in software that depends on the availability of CPUID leaves greater than 3.
		33:23		Reserved.
		34	Shared	**XD Bit Disable (R/W)** See Table 35-2.
		63:35		Reserved.

26FH	623	MTRRfix4K_F8000	Unique	
2FFH	767	IA32_MTRR_DEF_TYPE	Unique	**Default Memory Types (R/W)** See Table 35-2. See Section 11.11.2.1, "IA32_MTRR_DEF_TYPE MSR."
400H	1024	IA32_MC0_CTL	Unique	See Section 15.3.2.1, "IA32_MCi_CTL MSRs."
401H	1025	IA32_MC0_STATUS	Unique	See Section 15.3.2.2, "IA32_MCi_STATUS MSRS."
402H	1026	IA32_MC0_ADDR	Unique	See Section 15.3.2.3, "IA32_MCi_ADDR MSRs." The IA32_MC0_ADDR register is either not implemented or contains no address if the ADDRV flag in the IA32_MC0_STATUS register is clear. When not implemented in the processor, all reads and writes to this MSR will cause a general-protection exception.
404H	1028	IA32_MC1_CTL	Unique	See Section 15.3.2.1, "IA32_MCi_CTL MSRs."
405H	1029	IA32_MC1_STATUS	Unique	See Section 15.3.2.2, "IA32_MCi_STATUS MSRS."
406H	1030	IA32_MC1_ADDR	Unique	See Section 15.3.2.3, "IA32_MCi_ADDR MSRs." The IA32_MC1_ADDR register is either not implemented or contains no address if the ADDRV flag in the IA32_MC1_STATUS register is clear. When not implemented in the processor, all reads and writes to this MSR will cause a general-protection exception.
408H	1032	IA32_MC2_CTL	Unique	See Section 15.3.2.1, "IA32_MCi_CTL MSRs."
409H	1033	IA32_MC2_STATUS	Unique	See Section 15.3.2.2, "IA32_MCi_STATUS MSRS."
40AH	1034	IA32_MC2_ADDR	Unique	See Section 15.3.2.3, "IA32_MCi_ADDR MSRs." The IA32_MC2_ADDR register is either not implemented or contains no address if the ADDRV flag in the IA32_MC2_STATUS register is clear. When not implemented in the processor, all reads and writes to this MSR will cause a general-protection exception.
40CH	1036	MSR_MC4_CTL	Unique	See Section 15.3.2.1, "IA32_MCi_CTL MSRs."
40DH	1037	MSR_MC4_STATUS	Unique	See Section 15.3.2.2, "IA32_MCi_STATUS MSRS."
40EH	1038	MSR_MC4_ADDR	Unique	See Section 15.3.2.3, "IA32_MCi_ADDR MSRs." The MSR_MC4_ADDR register is either not implemented or contains no address if the ADDRV flag in the MSR_MC4_STATUS register is clear. When not implemented in the processor, all reads and writes to this MSR will cause a general-protection exception.
410H	1040	MSR_MC3_CTL		See Section 15.3.2.1, "IA32_MCi_CTL MSRs."
411H	1041	MSR_MC3_STATUS		See Section 15.3.2.2, "IA32_MCi_STATUS MSRS."

Table 35-37. MSRs in Intel® Core™ Solo, Intel® Core™ Duo Processors, and Dual-Core Intel® Xeon® Processor LV

Register Address		Register Name	Shared/ Unique	Bit Description
Hex	Dec			
412H	1042	MSR_MC3_ADDR	Unique	See Section 15.3.2.3, "IA32_MCi_ADDR MSRs." The MSR_MC3_ADDR register is either not implemented or contains no address if the ADDRV flag in the MSR_MC3_STATUS register is clear. When not implemented in the processor, all reads and writes to this MSR will cause a general-protection exception.
413H	1043	MSR_MC3_MISC	Unique	
414H	1044	MSR_MC5_CTL	Unique	
415H	1045	MSR_MC5_STATUS	Unique	
416H	1046	MSR_MC5_ADDR	Unique	
417H	1047	MSR_MC5_MISC	Unique	
480H	1152	IA32_VMX_BASIC	Unique	**Reporting Register of Basic VMX Capabilities (R/O)** See Table 35-2. See Appendix A.1, "Basic VMX Information" (If CPUID.01H:ECX.[bit 9])
481H	1153	IA32_VMX_PINBASED_ CTLS	Unique	**Capability Reporting Register of Pin-based VM-execution Controls (R/O)** See Appendix A.3, "VM-Execution Controls" (If CPUID.01H:ECX.[bit 9])
482H	1154	IA32_VMX_PROCBASED_ CTLS	Unique	**Capability Reporting Register of Primary Processor-based VM-execution Controls (R/O)** See Appendix A.3, "VM-Execution Controls" (If CPUID.01H:ECX.[bit 9])
483H	1155	IA32_VMX_EXIT_CTLS	Unique	**Capability Reporting Register of VM-exit Controls (R/O)** See Appendix A.4, "VM-Exit Controls" (If CPUID.01H:ECX.[bit 9])
484H	1156	IA32_VMX_ENTRY_CTLS	Unique	**Capability Reporting Register of VM-entry Controls (R/O)** See Appendix A.5, "VM-Entry Controls" (If CPUID.01H:ECX.[bit 9])
485H	1157	IA32_VMX_MISC	Unique	**Reporting Register of Miscellaneous VMX Capabilities (R/O)** See Appendix A.6, "Miscellaneous Data" (If CPUID.01H:ECX.[bit 9])
486H	1158	IA32_VMX_CR0_FIXED0	Unique	**Capability Reporting Register of CR0 Bits Fixed to 0 (R/O)** See Appendix A.7, "VMX-Fixed Bits in CR0" (If CPUID.01H:ECX.[bit 9])
487H	1159	IA32_VMX_CR0_FIXED1	Unique	**Capability Reporting Register of CR0 Bits Fixed to 1 (R/O)** See Appendix A.7, "VMX-Fixed Bits in CR0" (If CPUID.01H:ECX.[bit 9])
488H	1160	IA32_VMX_CR4_FIXED0	Unique	**Capability Reporting Register of CR4 Bits Fixed to 0 (R/O)** See Appendix A.8, "VMX-Fixed Bits in CR4" (If CPUID.01H:ECX.[bit 9])

Table 35-37. MSRs in Intel® Core™ Solo, Intel® Core™ Duo Processors, and Dual-Core Intel® Xeon® Processor LV

Register Address		Register Name	Shared/ Unique	Bit Description
Hex	Dec			
489H	1161	IA32_VMX_CR4_FIXED1	Unique	**Capability Reporting Register of CR4 Bits Fixed to 1 (R/O)** See Appendix A.8, "VMX-Fixed Bits in CR4" (If CPUID.01H:ECX.[bit 9])
48AH	1162	IA32_VMX_VMCS_ENUM	Unique	**Capability Reporting Register of VMCS Field Enumeration (R/O)** See Appendix A.9, "VMCS Enumeration" (If CPUID.01H:ECX.[bit 9])
48BH	1163	IA32_VMX_PROCBASED_ CTLS2	Unique	**Capability Reporting Register of Secondary Processor-based VM-execution Controls (R/O)** See Appendix A.3, "VM-Execution Controls" (If CPUID.01H:ECX.[bit 9] and IA32_VMX_PROCBASED_CTLS[bit 63])
600H	1536	IA32_DS_AREA	Unique	**DS Save Area (R/W)** See Table 35-2. See Section 18.13.4, "Debug Store (DS) Mechanism."
		31:0		**DS Buffer Management Area** Linear address of the first byte of the DS buffer management area.
		63:32		Reserved.
C000_ 0080H		IA32_EFER	Unique	See Table 35-2.
		10:0		Reserved.
		11		**Execute Disable Bit Enable**
		63:12		Reserved.

35.18 MSRS IN THE PENTIUM M PROCESSOR

Model-specific registers (MSRs) for the Pentium M processor are similar to those described in Section 35.19 for P6 family processors. The following table describes new MSRs and MSRs whose behavior has changed on the Pentium M processor.

Table 35-38. MSRs in Pentium M Processors

Register Address		Register Name	Bit Description
Hex	Dec		
0H	0	P5_MC_ADDR	See Section 35.20, "MSRs in Pentium Processors."
1H	1	P5_MC_TYPE	See Section 35.20, "MSRs in Pentium Processors."
10H	16	IA32_TIME_STAMP_COUNTER	See Section 17.14, "Time-Stamp Counter," and see Table 35-2.
17H	23	IA32_PLATFORM_ID	**Platform ID (R)** See Table 35-2. The operating system can use this MSR to determine "slot" information for the processor and the proper microcode update to load.

Table 35-38. MSRs in Pentium M Processors (Contd.)

Register Address		Register Name	Bit Description
Hex	Dec		
2AH	42	MSR_EBL_CR_POWERON	**Processor Hard Power-On Configuration** **(R/W)** Enables and disables processor features. **(R)** Indicates current processor configuration.
		0	Reserved.
		1	**Data Error Checking Enable (R)** 0 = Disabled Always 0 on the Pentium M processor.
		2	**Response Error Checking Enable (R)** 0 = Disabled Always 0 on the Pentium M processor.
		3	**MCERR# Drive Enable (R)** 0 = Disabled Always 0 on the Pentium M processor.
		4	**Address Parity Enable (R)** 0 = Disabled Always 0 on the Pentium M processor.
		6:5	Reserved.
		7	**BINIT# Driver Enable (R)** 1 = Enabled; 0 = Disabled Always 0 on the Pentium M processor.
		8	**Output Tri-state Enabled (R/O)** 1 = Enabled; 0 = Disabled
		9	**Execute BIST (R/O)** 1 = Enabled; 0 = Disabled
		10	**MCERR# Observation Enabled (R/O)** 1 = Enabled; 0 = Disabled Always 0 on the Pentium M processor.
		11	Reserved.
		12	**BINIT# Observation Enabled (R/O)** 1 = Enabled; 0 = Disabled Always 0 on the Pentium M processor.
		13	Reserved.
		14	**1 MByte Power on Reset Vector (R/O)** 1 = 1 MByte; 0 = 4 GBytes Always 0 on the Pentium M processor.
		15	Reserved.
		17:16	**APIC Cluster ID (R/O)** Always 00B on the Pentium M processor.

Table 35-38. MSRs in Pentium M Processors (Contd.)

Register Address		Register Name	Bit Description
Hex	Dec		
		18	**System Bus Frequency (R/O)** 0 = 100 MHz 1 = Reserved Always 0 on the Pentium M processor.
		19	Reserved.
		21: 20	**Symmetric Arbitration ID (R/O)** Always 00B on the Pentium M processor.
		26:22	Clock Frequency Ratio (R/O)
40H	64	MSR_LASTBRANCH_0	**Last Branch Record 0 (R/W)** One of 8 last branch record registers on the last branch record stack: bits 31-0 hold the 'from' address and bits 63-32 hold the to address. See also: ▪ Last Branch Record Stack TOS at 1C9H ▪ Section 17.12, "Last Branch, Interrupt, and Exception Recording (Pentium M Processors)"
41H	65	MSR_LASTBRANCH_1	**Last Branch Record 1 (R/W)** See description of MSR_LASTBRANCH_0.
42H	66	MSR_LASTBRANCH_2	**Last Branch Record 2 (R/W)** See description of MSR_LASTBRANCH_0.
43H	67	MSR_LASTBRANCH_3	**Last Branch Record 3 (R/W)** See description of MSR_LASTBRANCH_0.
44H	68	MSR_LASTBRANCH_4	**Last Branch Record 4 (R/W)** See description of MSR_LASTBRANCH_0.
45H	69	MSR_LASTBRANCH_5	**Last Branch Record 5 (R/W)** See description of MSR_LASTBRANCH_0.
46H	70	MSR_LASTBRANCH_6	**Last Branch Record 6 (R/W)** See description of MSR_LASTBRANCH_0.
47H	71	MSR_LASTBRANCH_7	**Last Branch Record 7 (R/W)** See description of MSR_LASTBRANCH_0.
119H	281	MSR_BBL_CR_CTL	
		63:0	Reserved.
11EH	281	MSR_BBL_CR_CTL3	
		0	**L2 Hardware Enabled (RO)** 1 = If the L2 is hardware-enabled 0 = Indicates if the L2 is hardware-disabled
		4:1	Reserved.

Table 35-38. MSRs in Pentium M Processors (Contd.)

Register Address		Register Name	Bit Description
Hex	Dec		
		5	**ECC Check Enable (RO)** This bit enables ECC checking on the cache data bus. ECC is always generated on write cycles. 0 = Disabled (default) 1 = Enabled For the Pentium M processor, ECC checking on the cache data bus is always enabled.
		7:6	Reserved.
		8	**L2 Enabled (R/W)** 1 = L2 cache has been initialized 0 = Disabled (default) Until this bit is set the processor will not respond to the WBINVD instruction or the assertion of the FLUSH# input.
		22:9	Reserved.
		23	**L2 Not Present (RO)** 0 = L2 Present 1 = L2 Not Present
		63:24	Reserved.
179H	377	IA32_MCG_CAP	
		7:0	**Count (RO)** Indicates the number of hardware unit error reporting banks available in the processor.
		8	**IA32_MCG_CTL Present (RO)** 1 = Indicates that the processor implements the MSR_MCG_CTL register found at MSR 17BH. 0 = Not supported.
		63:9	Reserved.
17AH	378	IA32_MCG_STATUS	
		0	**RIPV** When set, this bit indicates that the instruction addressed by the instruction pointer pushed on the stack (when the machine check was generated) can be used to restart the program. If this bit is cleared, the program cannot be reliably restarted.
		1	**EIPV** When set, this bit indicates that the instruction addressed by the instruction pointer pushed on the stack (when the machine check was generated) is directly associated with the error.
		2	**MCIP** When set, this bit indicates that a machine check has been generated. If a second machine check is detected while this bit is still set, the processor enters a shutdown state. Software should write this bit to 0 after processing a machine check exception.
		63:3	Reserved.

Table 35-38. MSRs in Pentium M Processors (Contd.)

Register Address		Register Name	Bit Description
Hex	Dec		
198H	408	IA32_PERF_STATUS	See Table 35-2.
199H	409	IA32_PERF_CTL	See Table 35-2.
19AH	410	IA32_CLOCK_MODULATION	**Clock Modulation (R/W).** See Table 35-2. See Section 14.7.3, "Software Controlled Clock Modulation."
19BH	411	IA32_THERM_INTERRUPT	**Thermal Interrupt Control (R/W)** See Table 35-2. See Section 14.7.2, "Thermal Monitor."
19CH	412	IA32_THERM_STATUS	**Thermal Monitor Status (R/W)** See Table 35-2. See Section 14.7.2, "Thermal Monitor."
19DH	413	MSR_THERM2_CTL	
		15:0	Reserved.
		16	**TM_SELECT (R/W)** Mode of automatic thermal monitor: 0 = Thermal Monitor 1 (thermally-initiated on-die modulation of the stop-clock duty cycle) 1 = Thermal Monitor 2 (thermally-initiated frequency transitions) If bit 3 of the IA32_MISC_ENABLE register is cleared, TM_SELECT has no effect. Neither TM1 nor TM2 will be enabled.
		63:16	Reserved.
1A0H	416	IA32_MISC_ENABLE	**Enable Miscellaneous Processor Features (R/W)** Allows a variety of processor functions to be enabled and disabled.
		2:0	Reserved.
		3	**Automatic Thermal Control Circuit Enable (R/W)** 1 = Setting this bit enables the thermal control circuit (TCC) portion of the Intel Thermal Monitor feature. This allows processor clocks to be automatically modulated based on the processor's thermal sensor operation. 0 = Disabled (default). The automatic thermal control circuit enable bit determines if the thermal control circuit (TCC) will be activated when the processor's internal thermal sensor determines the processor is about to exceed its maximum operating temperature. When the TCC is activated and TM1 is enabled, the processors clocks will be forced to a 50% duty cycle. BIOS must enable this feature. The bit should not be confused with the on-demand thermal control circuit enable bit.
		6:4	Reserved.
		7	**Performance Monitoring Available (R)** 1 = Performance monitoring enabled 0 = Performance monitoring disabled

Table 35-38. MSRs in Pentium M Processors (Contd.)

Register Address		Register Name	Bit Description
Hex	Dec		
		9:8	Reserved.
		10	**FERR# Multiplexing Enable (R/W)** 1 = FERR# asserted by the processor to indicate a pending break event within the processor 0 = Indicates compatible FERR# signaling behavior This bit must be set to 1 to support XAPIC interrupt model usage.
			Branch Trace Storage Unavailable (RO) 1 = Processor doesn't support branch trace storage (BTS) 0 = BTS is supported
		12	**Precise Event Based Sampling Unavailable (RO)** 1 = Processor does not support precise event-based sampling (PEBS); 0 = PEBS is supported. The Pentium M processor does not support PEBS.
		15:13	Reserved.
		16	**Enhanced Intel SpeedStep Technology Enable (R/W)** 1 = Enhanced Intel SpeedStep Technology enabled. On the Pentium M processor, this bit may be configured to be read-only.
		22:17	Reserved.
		23	**xTPR Message Disable (R/W)** When set to 1, xTPR messages are disabled. xTPR messages are optional messages that allow the processor to inform the chipset of its priority. The default is processor specific.
		63:24	Reserved.
1C9H	457	MSR_LASTBRANCH_TOS	**Last Branch Record Stack TOS (R/W)** Contains an index (bits 0-3) that points to the MSR containing the most recent branch record. See also: ▪ MSR_LASTBRANCH_0_FROM_IP (at 40H) ▪ Section 17.12, "Last Branch, Interrupt, and Exception Recording (Pentium M Processors)"
1D9H	473	MSR_DEBUGCTLB	**Debug Control (R/W)** Controls how several debug features are used. Bit definitions are discussed in the referenced section. See Section 17.12, "Last Branch, Interrupt, and Exception Recording (Pentium M Processors)."
1DDH	477	MSR_LER_TO_LIP	**Last Exception Record To Linear IP (R)** This area contains a pointer to the target of the last branch instruction that the processor executed prior to the last exception that was generated or the last interrupt that was handled. See Section 17.12, "Last Branch, Interrupt, and Exception Recording (Pentium M Processors)" and Section 17.13.2, "Last Branch and Last Exception MSRs."

Table 35-38. MSRs in Pentium M Processors (Contd.)

Register Address		Register Name	Bit Description
Hex	Dec		
1DEH	478	MSR_LER_FROM_LIP	**Last Exception Record From Linear IP (R)** Contains a pointer to the last branch instruction that the processor executed prior to the last exception that was generated or the last interrupt that was handled. See Section 17.12, "Last Branch, Interrupt, and Exception Recording (Pentium M Processors)" and Section 17.13.2, "Last Branch and Last Exception MSRs."
2FFH	767	IA32_MTRR_DEF_TYPE	**Default Memory Types (R/W)** Sets the memory type for the regions of physical memory that are not mapped by the MTRRs. See Section 11.11.2.1, "IA32_MTRR_DEF_TYPE MSR."
400H	1024	IA32_MC0_CTL	See Section 15.3.2.1, "IA32_MCi_CTL MSRs."
401H	1025	IA32_MC0_STATUS	See Section 15.3.2.2, "IA32_MCi_STATUS MSRS."
402H	1026	IA32_MC0_ADDR	See Section 14.3.2.3., "IA32_MCi_ADDR MSRs". The IA32_MC0_ADDR register is either not implemented or contains no address if the ADDRV flag in the IA32_MC0_STATUS register is clear. When not implemented in the processor, all reads and writes to this MSR will cause a general-protection exception.
404H	1028	IA32_MC1_CTL	See Section 15.3.2.1, "IA32_MCi_CTL MSRs."
405H	1029	IA32_MC1_STATUS	See Section 15.3.2.2, "IA32_MCi_STATUS MSRS."
406H	1030	IA32_MC1_ADDR	See Section 15.3.2.3, "IA32_MCi_ADDR MSRs." The IA32_MC1_ADDR register is either not implemented or contains no address if the ADDRV flag in the IA32_MC1_STATUS register is clear. When not implemented in the processor, all reads and writes to this MSR will cause a general-protection exception.
408H	1032	IA32_MC2_CTL	See Section 15.3.2.1, "IA32_MCi_CTL MSRs."
409H	1033	IA32_MC2_STATUS	See Chapter 15.3.2.2, "IA32_MCi_STATUS MSRS."
40AH	1034	IA32_MC2_ADDR	See Section 15.3.2.3, "IA32_MCi_ADDR MSRs." The IA32_MC2_ADDR register is either not implemented or contains no address if the ADDRV flag in the IA32_MC2_STATUS register is clear. When not implemented in the processor, all reads and writes to this MSR will cause a general-protection exception.
40CH	1036	MSR_MC4_CTL	See Section 15.3.2.1, "IA32_MCi_CTL MSRs."
40DH	1037	MSR_MC4_STATUS	See Section 15.3.2.2, "IA32_MCi_STATUS MSRS."
40EH	1038	MSR_MC4_ADDR	See Section 15.3.2.3, "IA32_MCi_ADDR MSRs." The MSR_MC4_ADDR register is either not implemented or contains no address if the ADDRV flag in the MSR_MC4_STATUS register is clear. When not implemented in the processor, all reads and writes to this MSR will cause a general-protection exception.
410H	1040	MSR_MC3_CTL	See Section 15.3.2.1, "IA32_MCi_CTL MSRs."
411H	1041	MSR_MC3_STATUS	See Section 15.3.2.2, "IA32_MCi_STATUS MSRS."

Table 35-38. MSRs in Pentium M Processors (Contd.)

Register Address		Register Name	Bit Description
Hex	Dec		
412H	1042	MSR_MC3_ADDR	See Section 15.3.2.3, "IA32_MCi_ADDR MSRs." The MSR_MC3_ADDR register is either not implemented or contains no address if the ADDRV flag in the MSR_MC3_STATUS register is clear. When not implemented in the processor, all reads and writes to this MSR will cause a general-protection exception.
600H	1536	IA32_DS_AREA	**DS Save Area (R/W)** See Table 35-2. Points to the DS buffer management area, which is used to manage the BTS and PEBS buffers. See Section 18.13.4, "Debug Store (DS) Mechanism."
		31:0	**DS Buffer Management Area** Linear address of the first byte of the DS buffer management area.
		63:32	Reserved.

35.19 MSRS IN THE P6 FAMILY PROCESSORS

The following MSRs are defined for the P6 family processors. The MSRs in this table that are shaded are available only in the Pentium II and Pentium III processors. Beginning with the Pentium 4 processor, some of the MSRs in this list have been designated as "architectural" and have had their names changed. See Table 35-2 for a list of the architectural MSRs.

Table 35-39. MSRs in the P6 Family Processors

Register Address		Register Name	Bit Description
Hex	Dec		
0H	0	P5_MC_ADDR	See Section 35.20, "MSRs in Pentium Processors."
1H	1	P5_MC_TYPE	See Section 35.20, "MSRs in Pentium Processors."
10H	16	TSC	See Section 17.14, "Time-Stamp Counter."
17H	23	IA32_PLATFORM_ID	**Platform ID (R)** The operating system can use this MSR to determine "slot" information for the processor and the proper microcode update to load.
		49:0	Reserved.
		52:50	**Platform Id (R)** Contains information concerning the intended platform for the processor. 52 51 50 0 0 0 Processor Flag 0 0 0 1 Processor Flag 1 0 1 0 Processor Flag 2 0 1 1 Processor Flag 3 1 0 0 Processor Flag 4 1 0 1 Processor Flag 5 1 1 0 Processor Flag 6 1 1 1 Processor Flag 7
		56:53	L2 Cache Latency Read.
		59:57	Reserved.

Table 35-39. MSRs in the P6 Family Processors (Contd.)

Register Address		Register Name	Bit Description
Hex	Dec		
		60	Clock Frequency Ratio Read.
		63:61	Reserved.
1BH	27	APIC_BASE	Section 10.4.4, "Local APIC Status and Location."
		7:0	Reserved.
		8	**Boot Strap Processor indicator Bit** 1 = BSP
		10:9	Reserved.
		11	**APIC Global Enable Bit - Permanent till reset** 1 = Enabled 0 = Disabled
		31:12	APIC Base Address.
		63:32	Reserved.
2AH	42	EBL_CR_POWERON	**Processor Hard Power-On Configuration** **(R/W)** Enables and disables processor features; **(R)** indicates current processor configuration.
		0	Reserved.[1]
		1	**Data Error Checking Enable (R/W)** 1 = Enabled 0 = Disabled
		2	**Response Error Checking Enable FRCERR Observation Enable (R/W)** 1 = Enabled 0 = Disabled
		3	**AERR# Drive Enable (R/W)** 1 = Enabled 0 = Disabled
		4	**BERR# Enable for Initiator Bus Requests (R/W)** 1 = Enabled 0 = Disabled
		5	Reserved.
		6	**BERR# Driver Enable for Initiator Internal Errors (R/W)** 1 = Enabled 0 = Disabled
		7	**BINIT# Driver Enable (R/W)** 1 = Enabled 0 = Disabled
		8	**Output Tri-state Enabled (R)** 1 = Enabled 0 = Disabled

Table 35-39. MSRs in the P6 Family Processors (Contd.)

Register Address		Register Name	Bit Description
Hex	Dec		
		9	**Execute BIST (R)** 1 = Enabled 0 = Disabled
		10	**AERR# Observation Enabled (R)** 1 = Enabled 0 = Disabled
		11	Reserved.
		12	**BINIT# Observation Enabled (R)** 1 = Enabled 0 = Disabled
		13	**In Order Queue Depth (R)** 1 = 1 0 = 8
		14	**1-MByte Power on Reset Vector (R)** 1 = 1MByte 0 = 4GBytes
		15	**FRC Mode Enable (R)** 1 = Enabled 0 = Disabled
		17:16	**APIC Cluster ID (R)**
		19:18	**System Bus Frequency (R)** 00 = 66MHz 10 = 100Mhz 01 = 133MHz 11 = Reserved
		21: 20	**Symmetric Arbitration ID (R)**
		25:22	**Clock Frequency Ratio (R)**
		26	**Low Power Mode Enable (R/W)**
		27	**Clock Frequency Ratio**
		63:28	Reserved.[1]
33H	51	TEST_CTL	**Test Control Register**
		29:0	Reserved.
		30	**Streaming Buffer Disable**
		31	**Disable LOCK#** Assertion for split locked access.
79H	121	BIOS_UPDT_TRIG	BIOS Update Trigger Register.
88H	136	BBL_CR_D0[63:0]	Chunk 0 data register D[63:0]: used to write to and read from the L2
89H	137	BBL_CR_D1[63:0]	Chunk 1 data register D[63:0]: used to write to and read from the L2
8AH	138	BBL_CR_D2[63:0]	Chunk 2 data register D[63:0]: used to write to and read from the L2

Table 35-39. MSRs in the P6 Family Processors (Contd.)

Register Address		Register Name	Bit Description
Hex	Dec		
8BH	139	BIOS_SIGN/BBL_CR_D3[63:0]	**BIOS Update Signature Register or Chunk 3 data register D[63:0]** Used to write to and read from the L2 depending on the usage model.
C1H	193	PerfCtr0 (PERFCTR0)	
C2H	194	PerfCtr1 (PERFCTR1)

413H	1043	MC3_MISC	Defined in MCA architecture but not implemented in the P6 family processors.

NOTES

1. Bit 0 of this register has been redefined several times, and is no longer used in P6 family processors.
2. The processor number feature may be disabled by setting bit 21 of the BBL_CR_CTL MSR (model-specific register address 119h) to "1". Once set, bit 21 of the BBL_CR_CTL may not be cleared. This bit is write-once. The processor number feature will be disabled until the processor is reset.
3. The Pentium III processor will prevent FSB frequency overclocking with a new shutdown mechanism. If the FSB frequency selected is greater than the internal FSB frequency the processor will shutdown. If the FSB selected is less than the internal FSB frequency the BIOS may choose to use bit 11 to implement its own shutdown policy.

35.20 MSRS IN PENTIUM PROCESSORS

The following MSRs are defined for the Pentium processors. The P5_MC_ADDR, P5_MC_TYPE, and TSC MSRs (named IA32_P5_MC_ADDR, IA32_P5_MC_TYPE, and IA32_TIME_STAMP_COUNTER in the Pentium 4 processor) are architectural; that is, code that accesses these registers will run on Pentium 4 and P6 family processors without generating exceptions (see Section 35.1, "Architectural MSRs"). The CESR, CTR0, and CTR1 MSRs are unique to

Pentium processors; code that accesses these registers will generate exceptions on Pentium 4 and P6 family processors.

Table 35-40. MSRs in the Pentium Processor

13H	19	CTR1	Section 18.21.3, "Events Counted."

CHAPTER 36
INTEL® PROCESSOR TRACE

36.1 OVERVIEW

Intel® Processor Trace (**Intel PT**) is an extension of Intel® Architecture that captures information about software execution using dedicated hardware facilities that cause only minimal performance perturbation to the software being traced. This information is collected in **data packets**. The initial implementations of Intel PT offer **control flow tracing**, which generates a variety of packets to be processed by a software decoder. The packets include timing, program flow information (e.g. branch targets, branch taken/not taken indications) and program-induced mode related information (e.g. Intel TSX state transitions, CR3 changes). These packets may be buffered internally before being sent to the memory subsystem or other output mechanism available in the platform. Debug software can process the trace data and reconstruct the program flow.

36.1.1 Features and Capabilities

Intel PT's control flow trace generates a variety of packets that, when combined with the binaries of a program by a post-processing tool, can be used to produce an exact execution trace. The packets record flow information such as instruction pointers (IP), indirect branch targets, and directions of conditional branches within contiguous code regions (basic blocks).

In addition, the packets record other contextual, timing, and bookkeeping information that enables both functional and performance debugging of applications. Intel PT has several control and filtering capabilities available to customize the tracing information collected and to append other processor state and timing information to enable debugging. For example, there are modes that allow packets to be filtered based on the current privilege level (CPL) or the value of CR3.

Configuration of the packet generation and filtering capabilities are programmed via a set of MSRs. The MSRs generally follow the naming convention of IA32_RTIT_*. The capability provided by these configuration MSRs are enumerated by CPUID, see Section 36.3. Details of the MSRs for configuring Intel PT are described in Section 36.2.5.

36.1.1.1 Packet Summary

After a tracing tool has enabled and configured the appropriate MSRs, the processor will collect and generate trace information in the following categories of packets (for more details on the packets, see Section 36.4):

- Packets about basic information on program execution: These include:
  - Packet Stream Boundary (**PSB**) packets: PSB packets act as 'heartbeats' that are generated at regular intervals (e.g., every 4K trace packet bytes). These packets allow the packet decoder to find the packet boundaries within the output data stream; a PSB packet should be the first packet that a decoder looks for when beginning to decode a trace.
  - Paging Information Packet (**PIP**): PIPs record modifications made to the CR3 register. This information, along with information from the operating system on the CR3 value of each process, allows the debugger to attribute linear addresses to their correct application source.
  - Time-Stamp Counter (**TSC**) packets: TSC packets aid in tracking wall-clock time, and contain some portion of the software-visible time-stamp counter.
  - Core Bus Ratio (**CBR**) packets: CBR packets contain the core:bus clock ratio.
  - Overflow (**OVF**) packets: OVF packets are sent when the processor experiences an internal buffer overflow, resulting in packets being dropped. This packet notifies the decoder of the loss and can help the decoder to respond to this situation.
- Packets about control flow information:
  - Taken Not-Taken (**TNT**) packets: TNT packets track the "direction" of direct conditional branches (taken or not taken).

— Target IP (**TIP**) packets: TIP packets record the target IP of indirect branches, exceptions, interrupts, and other branches or events. These packets can contain the IP, although that IP value may be compressed by eliminating upper bytes that match the last IP. There are various types of TIP packets; they are covered in more detail in Section 36.4.2.2.

— Flow Update Packets (**FUP**): FUPs provide the source IP addresses for asynchronous events (interrupt and exceptions), as well as other cases where the source address cannot be determined from the binary.

— **MODE** packets: These packets provide the decoder with important processor execution information so that it can properly interpret the dis-assembled binary and trace log. MODE packets have a variety of formats that indicate details such as the execution mode (16-bit, 32-bit, or 64-bit).

36.2 INTEL® PROCESSOR TRACE OPERATIONAL MODEL

This section describes the overall Intel Processor Trace mechanism and the essential concepts relevant to how it operates.

36.2.1 Change of Flow Instruction (COFI) Tracing

A basic program block is a section of code where no jumps or branches occur. The instruction pointers (IPs) in this block of code need not be traced, as the processor will execute them from start to end without redirecting code flow. Instructions such as branches, and events such as exceptions or interrupts, can change the program flow. These instructions and events that change program flow are called Change of Flow Instructions (COFI). There are three categories of COFI:

- Direct transfer COFI.
- Indirect transfer COFI.
- Far transfer COFI.

The following subsections describe the COFI events that result in trace packet generation. Table 36-1 lists branch instruction by COFI types. For detailed description of specific instructions, see *Intel® 64 and IA-32 Architectures Software Developer's Manual*.

Table 36-1. COFI Type for Branch Instructions

COFI Type	Instructions
Conditional Branch	JA, JAE, JB, JBE, JC, JCXZ< JECXZ, JRCXZ, JE, JG, JGE, JL, JLE, JNA, JNAE, JNB, JNBE, JNC, JNE, JNG, JNGE, JNL, JNLE, JNO, JNP, JNS, JNZ, JO, JP, JPE, JPO, JS, JZ, LOOP, LOOPE, LOOPNE, LOOPNZ, LOOPZ
Unconditional Direct Branch	JMP (E9 xx, EB xx), CALL (E8 xx)
Indirect Branch	JMP (FF /4), CALL (FF /2)
Near Ret	RET (C3, C2 xx)
Far Transfers	INT3, INTn, INTO, IRET, IRETD, IRETQ, JMP (EA xx, FF /5), CALL (9A xx, FF /3), RET (CB, CA xx), SYSCALL, SYSRET, SYSENTER, SYSEXIT, VMLAUNCH, VMRESUME

36.2.1.1 Direct Transfer COFI

Direct Transfer COFI are relative branches. This means that their target is an IP whose offset from the current IP is embedded in the instruction bytes. It is not necessary to indicate target of these instructions in the trace output since it can be obtained through the source disassembly. Conditional branches need to indicate only whether the branch is taken or not. Unconditional branches do not need any recording in the trace output. There are two sub-categories:

- **Conditional Branch (Jcc, J*CXZ) and LOOP**

  To track this type of instruction, the processor encodes a single bit (taken or not taken — TNT) to indicate the program flow after the instruction.

Jcc, J*CXZ, and LOOP can be traced with TNT bits. To improve the trace packet output efficiency, the processor will compact several TNT bits into a single packet.

- **Unconditional Direct Jumps**

  There is no trace output required for direct unconditional jumps (like JMP near relative or CALL near relative) since they can be directly inferred from the application assembly. Direct unconditional jumps do not generate a TNT bit or a Target IP packet, though TIP.PGD and TIP.PGE packets can be generated by unconditional direct jumps that toggle Intel PT enables (see Section 36.2.3).

36.2.1.2 Indirect Transfer COFI

Indirect transfer instructions involve updating the IP from a register or memory location. Since the register or memory contents can vary at any time during execution, there is no way to know the target of the indirect transfer until the register or memory contents are read. As a result, the disassembled code is not sufficient to determine the target of this type of COFI. Therefore, tracing hardware must send out the destination IP in the trace packet for debug software to determine the target address of the COFI. Note that this IP may be a linear or effective address (see Section 36.3.1.1).

An indirect transfer instruction generates a Target IP Packet (TIP) that contains the target address of the branch. There are two sub-categories:

- **Near JMP Indirect and Near Call Indirect**

  As previously mentioned, the target of an indirect COFI resides in the contents of either a register or memory location. Therefore, the processor must generate a packet that includes this target address to allow the decoder to determine the program flow.

- **Near RET**

  When a CALL instruction executes, it pushes onto the stack the address of the next instruction following the CALL. Upon completion of the call procedure, the RET instruction is often used to pop the return address off of the call stack and redirect code flow back to the instruction following the CALL.

  A RET instruction simply transfers program flow to the address it popped off the stack. Because a called procedure may change the return address on the stack before executing the RET instruction, debug software can be misled if it assumes that code flow will return to the instruction following the last CALL. Therefore, even for near RET, a Target IP Packet may be sent.

  — **RET Compression**

    A special case is applied if the target of the RET is consistent with what would be expected from tracking the CALL stack. If it is assured that the decoder has seen the corresponding CALL (with "corresponding" defined as the CALL with matching stack depth), and the RET target is the instruction after that CALL, the RET target may be "compressed". In this case, only a single TNT bit of "taken" is generated instead of a Target IP Packet. To ensure that the decoder will not be confused in cases of RET compression, only RETs that correspond to CALLs which have been seen since the last PSB packet may be compressed in a given logical processor. For details, see "Indirect Transfer Compression for Returns (RET)" in Section 36.4.2.2.

36.2.1.3 Far Transfer COFI

All operations that change the instruction pointer and are not near jumps are "far transfers". This includes exceptions, interrupts, traps, TSX aborts, and instructions that do far transfers.

All far transfers will produce a Target IP (TIP) packet, which provides the destination IP address. For those far transfers that cannot be inferred from the binary source (e.g., asynchronous events such as exceptions and interrupts), the TIP will be preceded by a Flow Update packet (FUP), which provides the source IP address at which the event was taken. Table 36-25 indicates exactly which IP will be included in the FUP generated by a far transfer.

36.2.2 Trace Filtering

Intel Processor Trace provides filtering capabilities, by which the debug/profile tool can control what code is traced.

36.2.2.1 Filtering by Current Privilege Level (CPL)

Intel PT provides the ability to configure a logical processor to generate trace packets only when CPL = 0, when CPL > 0, or regardless of CPL.

CPL filtering ensures that no IPs or other architectural state information associated with the filtered CPL can be seen in the log. For example, if the processor is configured to trace only when CPL > 0, and software executes SYSCALL (changing the CPL to 0), the destination IP of the SYSCALL will be suppressed from the generated packet (see the discussion of TIP.PGD in Section 36.4.2.5).

It should be noted that CPL is always 0 in real-address mode and that CPL is always 3 in virtual-8086 mode. To trace code in these modes, filtering should be configured accordingly.

When software is executing in a non-enabled CPL, ContextEn is cleared. See Section 36.2.3.1 for details.

36.2.2.2 Filtering by CR3

Intel PT supports a CR3-filtering mechanism by which the generation of packets containing architectural states can be enabled or disabled based on the value of CR3. A debugger can use CR3 filtering to trace only a single application without context switching the state of the RTIT MSRs. For the reconstruction of traces from software with multiple threads, debug software may wish to context-switch for the state of the RTIT MSRs (if the operating system does not provide context-switch support) to separate the output for the different threads (see Section 36.3.5, “Context Switch Consideration”).

To trace for only a single CR3 value, software can write that value to the IA32_RTIT_CR3_MATCH MSR, and set IA32_RTIT_CTL.CR3Filter. When CR3 value does not match IA32_RTIT_CR3_MATCH and IA32_RTIT_CTL.CR3Filter is 1, ContextEn is forced to 0, and packets containing architectural states will not be generated. Some other packets can be generated when ContextEn is 0; see Section 36.2.3.3 for details. When CR3 does match IA32_RTIT_CR3_MATCH (or when IA32_RTIT_CTL.CR3Filter is 0), CR3 filtering does not force ContextEn to 0 (although it could be 0 due to other filters or modes).

CR3 matches IA32_RTIT_CR3_MATCH if the two registers are identical for bits 63:12, or 63:5 when in PAE paging mode; the lower 5 bits of CR3 and IA32_RTIT_CR3_MATCH are ignored. CR3 filtering is independent of the value of CR0.PG.

When CR3 filtering is in use, PIP packets may still be seen in the log if the processor is configured to trace when CPL = 0 (IA32_RTIT_CTL.OS = 1). If not, no PIP packets will be seen.

36.2.2.3 Filtering by IP

Trace packet generation with configurable filtering by IP is supported if CPUID.(EAX=14H, ECX=0):EBX[bit 2] = 1. Intel PT can be configured to enable the generation of packets containing architectural states only when the processor is executing code within certain IP ranges. If the IP is outside of these ranges, generation of some packets is blocked.

IP filtering is enabled using the ADDRn_CFG fields in the IA32_RTIT_CTL MSR (Section 36.2.5.2), where the digit 'n' is a zero-based number that selects which address range is being configured. Each ADDRn_CFG field configures the use of the register pair IA32_RTIT_ADDRn_A and IA32_RTIT_ADDRn_B (Section 36.2.5.5). IA32_RTIT_ADDRn_A defines the base and IA32_RTIT_ADDRn_B specifies the limit of the range in which tracing is enabled. Thus each range, referred to as the ADDRn range, is defined by [IA32_RTIT_ADDRn_A. IA32_RTIT_ADDRn_B]. There can be multiple such ranges, software can query CPUID (Section 36.3.1) for the number of ranges supported on a processor.

Default behavior (ADDRn_CFG=0) defines no IP filter range, meaning FilterEn is always set. In this case code at any IP can be traced, though other filters, such as CR3 or CPL, could limit tracing. When ADDRn_CFG is set to enable IP filtering (see Section 36.3.1), tracing will commence when a taken branch or event is seen whose target address is in the ADDRn range.

While inside a tracing region and with FilterEn is set, leaving the tracing region may only be detected once a taken branch or event with a target outside the range is retired. If an ADDRn range is entered or exited by executing the next sequential instruction, rather than by a control flow transfer, FilterEn may not toggle immediately. See Section 36.2.3.5 for more details on FilterEn.

Note that these address range base and limit values are inclusive, such that the range includes the first and last instruction whose first instruction byte is in the ADDRn range.

Depending upon processor implementation, IP filtering may be based on linear or effective address. This can cause different behavior between implementations if CSbase is not equal to zero or in real mode. See Section 36.3.1.1 for details. Software can query CPUID to determine filters are based on linear or effective address (Section 36.3.1).

Note that some packets, such as MTC (Section 36.3.7) and other timing packets, do not depend on FilterEn. For details on which packets depend on FilterEn, and hence are impacted by IP filtering, see Section 36.4.1.

TraceStop

The ADDRn ranges can also be configured to cause tracing to be disabled upon entry to the specified region. This is intended for cases where unexpected code is executed, and the user wishes to immediately stop generating packets in order to avoid overwriting previously written packets.

The TraceStop mechanism works much the same way that IP filtering does, and uses the same address comparison logic. The TraceStop region base and limit values are programmed into one or more ADDRn ranges, but IA32_RTIT_CTL.ADDRn_CFG is configured with the TraceStop encoding. Like FilterEn, TraceStop is detected when a taken branch or event lands in a TraceStop region.

Further, TraceStop requires that TriggerEn=1 at the beginning of the branch/event, and ContextEn=1 upon completion of the branch/event. When this happens, the CPU will set IA32_RTIT_STATUS.Stopped, thereby clearing TriggerEn and hence disabling packet generation. This may generate a TIP.PGD packet with the target IP of the branch or event that entered the TraceStop region. Finally, a TraceStop packet will be inserted, to indicate that the condition was hit.

If a TraceStop condition is encountered during buffer overflow (Section 36.3.8), it will not be dropped, but will instead be signaled once the overflow has resolved.

Note that a TraceStop event does not guarantee that all internally buffered packets are flushed out of internal buffers. To ensure that this has occurred, the user should clear TraceEn.

To resume tracing after a TraceStop event, the user must first disable Intel PT by clearing IA32_RTIT_CTL.TraceEn before the IA32_RTIT_STATUS.Stopped bit can be cleared. At this point Intel PT can be reconfigured, and tracing resumed.

Note that the IA32_RTIT_STATUS.Stopped bit can also be set using the ToPA STOP bit. See Section 36.2.4.2.

IP Filtering Example

The following table gives an example of IP filtering behavior. Assume that IA32_RTIT_ADDRn_A = the IP of RangeBase, and that IA32_RTIT_ADDRn_B = the IP of RangeLimit, while IA32_RTIT_CTL.ADDRn_CFG = 0x1 (enable ADDRn range as a FilterEn range).

Table 36-2. IP Filtering Packet Example

Code Flow	Packets

`Bar:`
`  jmp RangeBase // jump into filter range`
`RangeBase:`
`  jcc Foo // not taken`
`  add eax, 1`
`Foo:`
`  jmp RangeLimit+1 // jump out of filter range`
`RangeLimit:`
`  nop`
`  jcc Bar`
	TIP.PGE(RangeBase)
	TNT(0)
	TIP.PGD(RangeLimit+1)

IP Filtering and TraceStop

It is possible for the user to configure IP filter range(s) and TraceStop range(s) that overlap. In this case, code executing in the non-overlapping portion of either range will behave as would be expected from that range. Code executing in the overlapping range will get TraceStop behavior.

36.2.3 Packet Generation Enable Controls

Intel Processor Trace includes a variety of controls that determine whether a packet is generated. In general, most packets are sent only if Packet Enable (**PacketEn**) is set. PacketEn is an internal state maintained in hardware in response to software configurable enable controls, PacketEn is not visible to software directly. The relationship of PacketEn to the software-visible controls in the configuration MSRs is described in this section.

36.2.3.1 Packet Enable (PacketEn)

When PacketEn is set, the processor is in the mode that Intel PT is monitoring and all packets can be generated to log what is being executed. PacketEn is composed of other states according to this relationship:

```
PacketEn ← TriggerEn AND ContextEn AND FilterEn AND BranchEn
```

These constituent controls are detailed in the following subsections.

PacketEn ultimately determines when the processor is tracing. When PacketEn is set, all control flow packets are enabled. When PacketEn is clear, no control flow packets are generated, though other packets (timing and bookkeeping packets) may still be sent. See Section 36.2.4 for details of PacketEn and packet generation.

Note that, on processors that do not support IP filtering (i.e., CPUID.(EAX=14H, ECX=0):EBX.IPFILT_WRSTPRSV[bit 2] = 0), FilterEn is treated as always set.

36.2.3.2 Trigger Enable (TriggerEn)

Trigger Enable (**TriggerEn**) is the primary indicator that trace packet generation is active. TriggerEn is set when IA32_RTIT_CTL.TraceEn is set, and cleared by any of the following conditions:

- TraceEn is cleared by software,
- A TraceStop condition is encountered and IA32_RTIT_STATUS.Stopped is set,
- IA32_RTIT_STATUS.Error is set due to an operational error (see Section 36.3.9).

Software can discover the current TriggerEn value by reading the IA32_RTIT_STATUS.TriggerEn bit. When TriggerEn is clear, tracing is inactive and no packets are generated.

36.2.3.3 Context Enable (ContextEn)

Context Enable (**ContextEn**) indicates whether the processor is in the state or mode that software configured hardware to trace. For example, if execution with CPL = 0 code is not being traced (IA32_RTIT_CTL.OS = 0), then ContextEn will be 0 when the processor is in CPL0.

Software can discover the current ContextEn value by reading the IA32_RTIT_STATUS.ContextEn bit. ContextEn is defined as follows:

```
ContextEn = !((IA32_RTIT_CTL.OS = 0 AND CPL = 0) OR
(IA32_RTIT_CTL.USER = 0 AND CPL > 0) OR (IS_IN_A_PRODUCTION_ENCLAVE[1]) OR
(IA32_RTIT_CTL.CR3Filter = 1 AND IA32_RTIT_CR3_MATCH does not match CR3)
```

If the clearing of ContextEn causes PacketEn to be cleared, a Packet Generation Disable (TIP.PGD) packet is generated, but its IP payload is suppressed. If the setting of ContextEn causes PacketEn to be set, a Packet Generation Enable (TIP.PGE) packet is generated.

When ContextEn is 0, control flow packets (TNT, FUP, TIP.*, MODE.*) are not generated, and no Linear Instruction Pointers (LIPs) are exposed. However, some packets, such as MTC and PSB (see Section 36.4.2.16 and Section 36.4.2.17), may still be generated while ContextEn is 0. For details of which packets are generated only when ContextEn is set, see Section 36.4.1.

The processor does not update ContextEn when TriggerEn = 0.

The value of ContextEn will toggle only when TriggerEn = 1.

---

1. Trace packets generation is disabled in a production enclave, see Section 36.2.6.3. See *Intel® Software Guard Extensions Programming Reference* about differences between a production enclave and a debug enclave.

36.2.3.4 Branch Enable (BranchEn)

This value is based purely on the IA32_RTIT_CTL.BranchEn value. If **BranchEn** is not set, then relevant COFI packets (TNT, TIP*, FUP, MODE.*) are suppressed. Other packets related to timing (TSC, TMA, MTC, CYC), as well as PSB, will be generated normally regardless. Further, PIP and VMCS continue to be generated, as indicators of what software is running.

36.2.3.5 Filter Enable (FilterEn)

Filter Enable indicates that the Instruction Pointer (IP) is within the range of IPs that Intel PT is configured to watch. Software can get the state of Filter Enable by a RDMSR of IA32_RTIT_STATUS.FilterEn. For details on configuration and use of IP filtering, see Section 36.2.2.3.

On clearing of FilterEn that also clears PacketEn, a Packet Generation Disable (TIP.PGD) will be generated, but unlike the ContextEn case, the IP payload may not be suppressed. For direct, unconditional branches, as well as for indirect branches (including RETs), the PGD generated by leaving the tracing region and clearing FilterEn will contain the target IP. This means that IPs from outside the configured range can be exposed in the trace, as long as they are within context.

When FilterEn is 0, control flow packets are not generated (e.g., TNT, TIP). However, some packets, such as PIP, MTC, and PSB, may still be generated while FilterEn is clear. For details on packet enable dependencies, see Section 36.4.1.

After TraceEn is set, FilterEn is set to 1 at all times if there is no IP filter range configured by software (IA32_RTIT_CTL.ADDRn_CFG != 1, for all n), or if the processor does not support IP filtering (i.e., CPUID.(EAX=14H, ECX=0):EBX.IPFILT_WRSTPRSV[bit 2] = 0). FilterEn will toggle only when TraceEn=1 and ContextEn=1, and when at least one range is configured for IP filtering.

36.2.4 Trace Output

Intel PT output should be viewed independently from trace content and filtering mechanisms. The options available for trace output can vary across processor generations and platforms.

Trace output is written out using one of the following output schemes, as configured by the ToPA and FabricEn bit fields of IA32_RTIT_CTL (see Section 36.2.5.2):

- A single, contiguous region of physical address space.
- A collection of variable-sized regions of physical memory. These regions are linked together by tables of pointers to those regions, referred to as Table of Physical Addresses (**ToPA**). The trace output stores bypass the caches and the TLBs, but are not serializing. This is intended to minimize the performance impact of the output.
- A platform-specific trace transport subsystem.

Regardless of the output scheme chosen, Intel PT stores bypass the processor caches by default. This ensures that they don't consume precious cache space, but they do not have the serializing aspects associated with un-cacheable (UC) stores. Software should avoid using MTRRs to mark any portion of the Intel PT output region as UC, as this may override the behavior described above and force Intel PT stores to UC, thereby incurring severe performance impact.

There is no guarantee that a packet will be written to memory or other trace endpoint after some fixed number of cycles after a packet-producing instruction executes. The only way to assure that all packets generated have reached their endpoint is to clear TraceEn and follow that with a store, fence, or serializing instruction; doing so ensures that all buffered packets are flushed out of the processor.

36.2.4.1 Single Range Output

When IA32_RTIT_CTL.ToPA and IA32_RTIT_CTL.FabricEn bits are clear, trace packet output is sent to a single, contiguous memory (or MMIO if DRAM is not available) range defined by a base address in IA32_RTIT_OUTPUT_BASE (Section 36.2.5.7) and mask value in IA32_RTIT_OUTPUT_MASK_PTRS (Section 36.2.5.8). The current write pointer in this range is also stored in IA32_RTIT_OUTPUT_MASK_PTRS. This output range is circular, meaning that when the writes wrap around the end of the buffer they begin again at the base address.

This output method is best suited for cases where Intel PT output is either:

- Configured to be directed to a sufficiently large contiguous region of DRAM.
- Configured to go to an MMIO debug port, in order to route Intel PT output to a platform-specific trace endpoint (e.g., JTAG). In this scenario, a specific range of addresses is written in a circular manner, and SoC will intercept these writes and direct them to the proper device. Repeated writes to the same address do not overwrite each other, but are accumulated by the debugger, and hence no data is lost by the circular nature of the buffer.

The processor will determine the address to which to write the next trace packet output byte as follows:

```
OutputBase[63:0] ← IA32_RTIT_OUTPUT_BASE[63:0]

OutputMask[63:0] ← ZeroExtend64(IA32_RTIT_OUTPUT_MASK_PTRS[31:0])

OutputOffset[63:0] ← ZeroExtend64(IA32_RTIT_OUTPUT_MASK_PTRS[63:32])

trace_store_phys_addr ← (OutputBase & ~OutputMask) + (OutputOffset & OutputMask)
```

Single-Range Output Errors

If the output base and mask are not properly configured by software, an operational error (see Section 36.3.9) will be signaled, and tracing disabled. Error scenarios with single-range output are:

- Mask value is non-contiguous.

  IA32_RTIT_OUTPUT_MASK_PTRS.MaskOrTablePointer value has a 0 in a less significant bit position than the most significant bit containing a 1.
- Base address and Mask are mis-aligned, and have overlapping bits set.

  IA32_RTIT_OUTPUT_BASE && IA32_RTIT_OUTPUT_MASK_PTRS.MaskOrTableOffset > 0.
- Illegal Output Offset

  IA32_RTIT_OUTPUT_MASK_PTRS.OutputOffset is greater than the mask value (IA32_RTIT_OUTPUT_MASK_PTRS.MaskOrTableOffset).

Also note that errors can be signaled due to trace packet output overlapping with restricted memory, see Section 36.2.4.4.

36.2.4.2 Table of Physical Addresses (ToPA)

When IA32_RTIT_CTL.ToPA is set and IA32_RTIT_CTL.FabricEn is clear, the ToPA output mechanism is utilized. The ToPA mechanism uses a linked list of tables; see Figure 36-1 for an illustrative example. Each entry in the table contains some attribute bits, a pointer to an output region, and the size of the region. The last entry in the table may hold a pointer to the next table. This pointer can either point to the top of the current table (for circular array) or to the base of another table. The table size is not fixed, since the link to the next table can exist at any entry.

The processor treats the various output regions referenced by the ToPA table(s) as a unified buffer. This means that a single packet may span the boundary between one output region and the next.

The ToPA mechanism is controlled by three values maintained by the processor:

- **proc_trace_table_base.**
  This is the physical address of the base of the current ToPA table. When tracing is enabled, the processor loads this value from the IA32_RTIT_OUTPUT_BASE MSR. While tracing is enabled, the processor updates the IA32_RTIT_OUTPUT_BASE MSR with changes to proc_trace_table_base, but these updates may not be synchronous to software execution. When tracing is disabled, the processor ensures that the MSR contains the latest value of proc_trace_table_base.
- **proc_trace_table_offset.**
  This indicates the entry of the current table that is currently in use. (This entry contains the address of the current output region.) When tracing is enabled, the processor loads this value from bits 31:7 (MaskOrTableOffset) of the IA32_RTIT_OUTPUT_MASK_PTRS. While tracing is enabled, the processor updates IA32_RTIT_OUTPUT_MASK_PTRS.MaskOrTableOffset with changes to proc_trace_table_offset, but these updates may not be synchronous to software execution. When tracing is disabled, the processor ensures that the MSR contains the latest value of proc_trace_table_offset.
- **proc_trace_output_offset.**
  This a pointer into the current output region and indicates the location of the next write. When tracing is

enabled, the processor loads this value from bits 63:32 (OutputOffset) of the IA32_RTIT_OUTPUT_MASK_PTRS. While tracing is enabled, the processor updates IA32_RTIT_OUTPUT_MASK_PTRS.OutputOffset with changes to proc_trace_output_offset, but these updates may not be synchronous to software execution. When tracing is disabled, the processor ensures that the MSR contains the latest value of proc_trace_output_offset.

Figure 36-1 provides an illustration (not to scale) of the table and associated pointers.

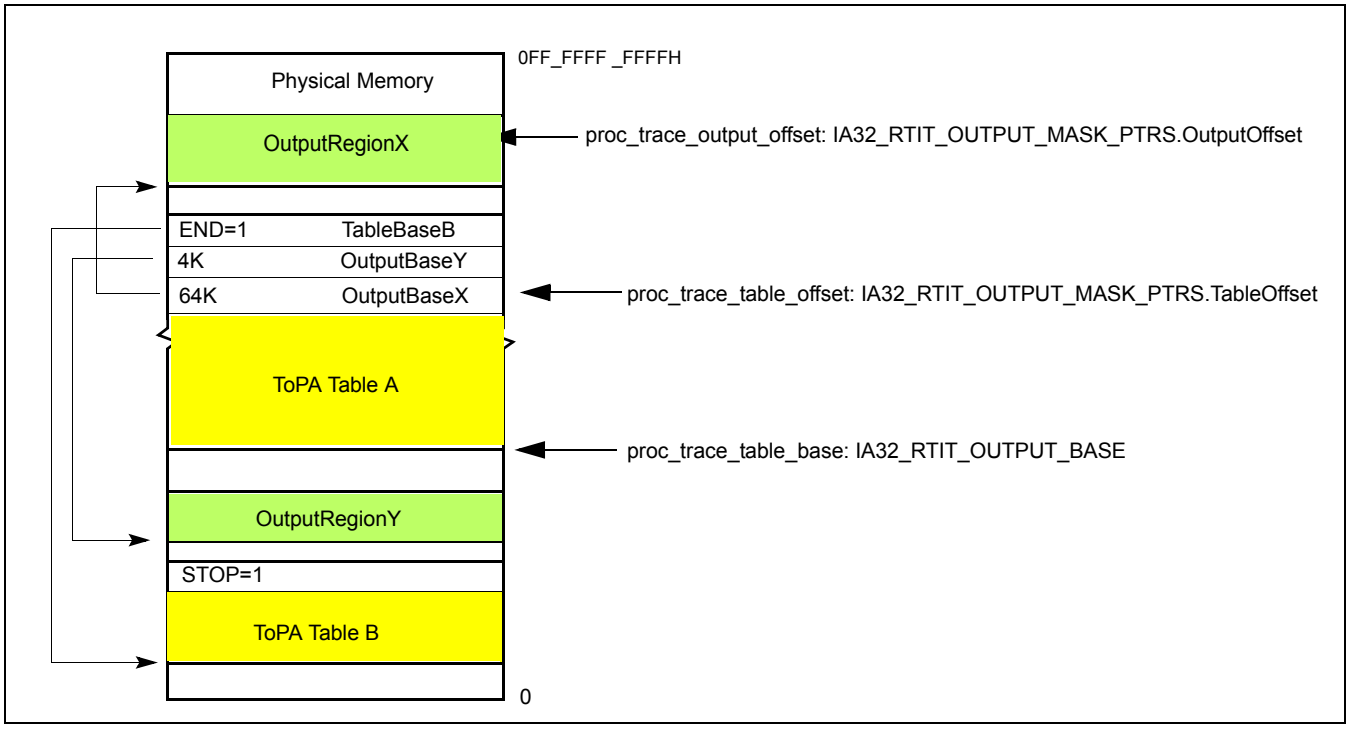

Figure 36-1. ToPA Memory Illustration

With the ToPA mechanism, the processor writes packets to the current output region (identified by proc_trace_table_base and the proc_trace_table_offset). The offset within that region to which the next byte will be written is identified by proc_trace_output_offset. When that region is filled with packet output (thus proc_trace_output_offset = RegionSize–1), proc_trace_table_offset is moved to the next ToPA entry, proc_trace_output_offset is set to 0, and packet writes begin filling the new output region specified by proc_trace_table_offset.

As packets are written out, each store derives its physical address as follows:

```
trace_store_phys_addr ← Base address from current ToPA table entry +
proc_trace_output_offset
```

Eventually, the regions represented by all entries in the table may become full, and the final entry of the table is reached. An entry can be identified as the final entry because it has either the END or STOP attribute. The END attribute indicates that the address in the entry does not point to another output region, but rather to another ToPA table. The STOP attribute indicates that tracing will be disabled once the corresponding region is filled. See Section 36.2.4.2 for details on STOP.

When an END entry is reached, the processor loads proc_trace_table_base with the base address held in this END entry, thereby moving the current table pointer to this new table. The proc_trace_table_offset is reset to 0, as is the proc_trace_output_offset, and packet writes will resume at the base address indicated in the first entry.

If the table has no STOP or END entry, and trace-packet generation remains enabled, eventually the maximum table size will be reached (proc_trace_table_offset = FFFFFFFFH). In this case, the proc_trace_table_offset and proc_trace_output_offset are reset to 0 (wrapping back to the beginning of the current table) once the last output region is filled.

It is important to note that processor updates to the IA32_RTIT_OUTPUT_BASE and IA32_RTIT_OUTPUT_MASK_PTRS MSRs are asynchronous to instruction execution. Thus, reads of these MSRs while Intel PT is enabled may return stale values. Like all IA32_RTIT_* MSRs, the values of these MSRs should not be trusted or saved unless trace packet generation is first disabled by clearing IA32_RTIT_CTL.TraceEn. This ensures that he output MSR values account for all packets generated to that point, after which the output MSR values will be frozen until tracing resumes. [1]

The processor may cache internally any number of entries from the current table or from tables that it references (directly or indirectly). If tracing is enabled, the processor may ignore or delay detection of modifications to these tables. To ensure that table changes are detected by the processor in a predictable manner, software should clear TraceEn before modifying the current table (or tables that it references) and only then re-enable packet generation.

Single Output Region ToPA Implementation

The first processor generation to implement Intel PT supports only ToPA configurations with a single ToPA entry followed by an END entry that points back to the first entry (creating one circular output buffer). Such processors enumerate CPUID.(EAX=14H,ECX=0):ECX.MENTRY[bit 1] = 0 and CPUID.(EAX=14H,ECX=0):ECX.TOPAOUT[bit 0] = 1.

If CPUID.(EAX=14H,ECX=0):ECX.MENTRY[bit 1] = 0, ToPA tables can hold only one output entry, which must be followed by an END=1 entry which points back to the base of the table. Hence only one contiguous block can be used as output.

The lone output entry can have INT or STOP set, but nonetheless must be followed by an END entry as described above. Note that, if INT=1, the PMI will actually be delivered before the region is filled.

ToPA Table Entry Format

The format of ToPA table entries is shown in Figure 36-2. The size of the address field is determined by the processor's physical-address width (MAXPHYADDR) in bits, as reported in CPUID.80000008H:EAX[7:0].

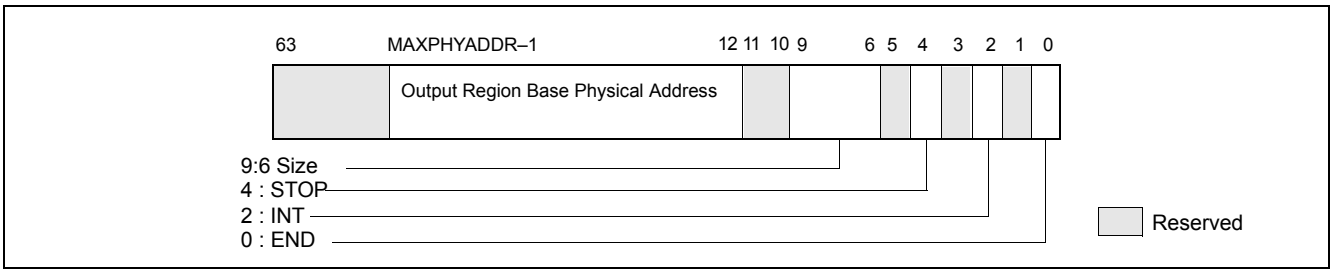

Figure 36-2. Layout of ToPA Table Entry

Table 36-3 describes the details of the ToPA table entry fields. If reserved bits are set to 1, an error is signaled.

Table 36-3. ToPA Table Entry Fields

ToPA Entry Field	Description
Output Region Base Physical Address	If END=0, this is the base physical address of the output region specified by this entry. Note that all regions must be aligned based on their size. Thus a 2M region must have bits 20:12 clear. If the region is not properly aligned, an operational error will be signaled when the entry is reached. If END=1, this is the 4K-aligned base physical address of the next ToPA table (which may be the base of the current table, or the first table in the linked list if a circular buffer is desired). If the processor supports only a single ToPA output region (see above), this address must be the value currently in the IA32_RTIT_OUTPUT_BASE MSR.

1. Although WRMSR is a serializing instruction, the execution of WRMSR that forces packet writes by clearing TraceEn does not itself cause these writes to be globally observed.

Table 36-3. ToPA Table Entry Fields

ToPA Entry Field	Description
Size	Indicates the size of the associated output region. Encodings are: 0: 4K, 1: 8K, 2: 16K, 3: 32K, 4: 64K, 5: 128K, 6: 256K, 7: 512K, 8: 1M, 9: 2M, 10: 4M, 11: 8M, 12: 16M, 13: 32M, 14: 64M, 15: 128M This field is ignored if END=1.
STOP	When the output region indicated by this entry is filled, software should disable packet generation. This will be accomplished by setting IA32_RTIT_STATUS.Stopped, which clears TriggerEn. This bit must be 0 if END=1; otherwise it is treated as reserved bit violation (see ToPA Errors).
INT	When the output region indicated by this entry is filled, signal Perfmon LVT interrupt. Note that if both INT and STOP are set in the same entry, the STOP will happen before the INT. Thus the interrupt handler should expect that the IA32_RTIT_STATUS.Stopped bit will be set, and will need to be reset before tracing can be resumed. This bit must be 0 if END=1; otherwise it is treated as reserved bit violation (see ToPA Errors).
END	If set, indicates that this is an END entry, and thus the address field points to a table base rather than an output region base. If END=1, INT and STOP must be set to 0; otherwise it is treated as reserved bit violation (see ToPA Errors). The Size field is ignored in this case. If the processor supports only a single ToPA output region (see above), END must be set in the second table entry.

ToPA STOP

Each ToPA entry has a STOP bit. If this bit is set, the processor will set the IA32_RTIT_STATUS.Stopped bit when the corresponding trace output region is filled. This will clear TriggerEn and thereby cease packet generation. See Section 36.2.5.4 for details on IA32_RTIT_STATUS.Stopped. This sequence is known as "ToPA Stop".

No TIP.PGD packet will be seen in the output when the ToPA stop occurs, since the disable happens only when the region is already full. When this occurs, output ceases after the last byte of the region is filled, which may mean that a packet is cut off in the middle. Any packets remaining in internal buffers are lost and cannot be recovered.

When ToPA stop occurs, the IA32_RTIT_OUTPUT_BASE MSR will hold the base address of the table whose entry had STOP=1. IA32_RTIT_OUTPUT_MASK_PTRS.MaskOrTableOffset will hold the index value for that entry, and the IA32_RTIT_OUTPUT_MASK_PTRS.OutputOffset should be set to the size of the region.

Note that this means the offset pointer is pointing to the next byte after the end of the region, a configuration that would produce an operational error if the configuration remained when tracing is re-enabled with IA32_RTIT_STATUS.Stopped cleared.

ToPA PMI

Each ToPA entry has an INT bit. If this bit is set, the processor will signal a performance-monitoring interrupt (PMI) when the corresponding trace output region is filled. This interrupt is not precise, and it is thus likely that writes to the next region will occur by the time the interrupt is taken.

The following steps should be taken to configure this interrupt:

1. Enable PMI via the LVT Performance Monitor register (at MMIO offset 340H in xAPIC mode; via MSR 834H in x2APIC mode). See *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3B* for more details on this register. For ToPA PMI, set all fields to 0, save for the interrupt vector, which can be selected by software.
2. Set up an interrupt handler to service the interrupt vector that a ToPA PMI can raise.
3. Set the interrupt flag by executing STI.
4. Set the INT bit in the ToPA entry of interest and enable packet generation, using the ToPA output option. Thus, TraceEn=ToPA=1 in the IA32_RTIT_CTL MSR.

Once the INT region has been filled with packet output data, the interrupt will be signaled. This PMI can be distinguished from others by checking bit 55 (Trace_ToPA_PMI) of the IA32_PERF_GLOBAL_STATUS MSR (MSR 38EH). Once the ToPA PMI handler has serviced the relevant buffer, writing 1 to bit 55 of the MSR at 390H (IA32_GLOBAL_STATUS_RESET) clears IA32_PERF_GLOBAL_STATUS.Trace_ToPA_PMI.

Intel PT is not frozen on PMI, and thus the interrupt handler will be traced (though filtering can prevent this). The IA32_DEBUGCTL.Freeze_Perfmon_on_PMI setting will be applied on ToPA PMI just as on other PMIs, and hence Perfmon counters are frozen.

Assuming the PMI handler wishes to read any buffered packets for persistent output, software should first disable packet generation by clearing TraceEn. This ensures that all buffered packets are written to memory and avoids tracing of the PMI handler. The configuration MSRs can then be used to determine where tracing has stopped. If packet generation is disabled by the handler, it should then be manually re-enabled before the IRET if continued tracing is desired.

ToPA PMI and Single Output Region ToPA Implementation

A processor that supports only a single ToPA output region implementation (such that only one output region is supported; see above) will attempt to signal a ToPA PMI interrupt before the output wraps and overwrites the top of the buffer. To support this functionality, the PMI handler should disable packet generation as soon as possible.

Due to PMI skid, it is possible, in rare cases, that the wrap will have occurred before the PMI is delivered. Software can avoid this by setting the STOP bit in the ToPA entry (see Table 36-3); this will disable tracing once the region is filled, and no wrap will occur. This approach has the downside of disabling packet generation so that some of the instructions that led up to the PMI will not be traced. If the PMI skid is significant enough to cause the region to fill and tracing to be disabled, the PMI handler will need to clear the IA32_RTIT_STATUS.Stopped indication before tracing can resume.

ToPA PMI and XSAVES/XRSTORS State Handling

In some cases the ToPA PMI may be taken after completion of an XSAVES instruction that switches Intel PT state, and in such cases any modification of Intel PT MSRs within the PMI handler will not persist when the saved Intel PT context is later restored with XRSTORS. To account for such a scenario, it is recommended that the Intel PT output configuration be modified by altering the ToPA tables themselves, rather than the Intel PT output MSRs.

Table 36-4 depicts a recommended PMI handler algorithm for managing multi-region ToPA output and handling ToPA PMIs that may arrive between XSAVES and XRSTORS. This algorithm is flexible to allow software to choose between adding entries to the current ToPA table, adding a new ToPA table, or using the current ToPA table as a circular buffer. It assumes that the ToPA entry that triggers the PMI is not the last entry in the table, which is the recommended treatment.

Table 36-4. Algorithm to Manage Intel PT ToPA PMI and XSAVES/XRSTORS

Pseudo Code Flow

```
IF (IA32_PERF_GLOBAL_STATUS.ToPA)
    Save IA32_RTIT_CTL value;
    IF ( IA32_RTIT_CTL.TraceEN )
        Disable Intel PT by clearing TraceEn;
    FI;
    IF ( there is space available to grow the current ToPA table )
        Add one or more ToPA entries after the last entry in the ToPA table;
        Point new ToPA entry address field(s) to new output region base(s);
    ELSE
        Modify an upcoming ToPA entry in the current table to have END=1;
        IF (output should transition to a new ToPA table )
            Point the address of the "END=1" entry of the current table to the new table base;
        ELSE
            /* Continue to use the current ToPA table, make a circular. */
            Point the address of the "END=1"l entry to the base of the current table;
            Modify the ToPA entry address fields for filled output regions to point to new, unused output regions;
            /* Filled regions are those with index in the range of 0 to (IA32_RTIT_MASK_PTRS.MaskOrTableOffset -1). */
        FI;
      FI;
      Restore saved IA32_RTIT_CTL.value;
FI;
```

ToPA Errors

When a malformed ToPA entry is found, an **operation error** results (see Section 36.3.9). A malformed entry can be any of the following:

1. **ToPA entry reserved bit violation**.
   This describes cases where a bit marked as reserved in Section 36.2.4.2 above is set to 1.
2. **ToPA alignment violation**.
   This includes cases where illegal ToPA entry base address bits are set to 1:
   a. ToPA table base address is not 4KB-aligned. The table base can be from a WRMSR to IA32_RTIT_OUTPUT_BASE, or from a ToPA entry with END=1.
   b. ToPA entry base address is not aligned to the ToPA entry size (e.g., a 2MB region with base address[20:12] not equal to 0).
   c. ToPA entry base address sets upper physical address bits not supported by the processor.
3. **Illegal ToPA Output Offset** (if IA32_RTIT_STATUS.Stopped=0).
   IA32_RTIT_OUTPUT_MASK_PTRS.OutputOffset is greater than or equal to the size of the current ToPA output region size.
4. **ToPA rules violations**.
   These are similar to ToPA entry reserved bit violations; they are cases when a ToPA entry is encountered with illegal field combinations. They include the following:
   a. Setting the STOP or INT bit on an entry with END=1.
   b. Setting the END bit in entry 0 of a ToPA table.
   c. On processors that support only a single ToPA entry (see above), two additional illegal settings apply:
      i) ToPA table entry 1 with END=0.
      ii) ToPA table entry 1 with base address not matching the table base.

In all cases, the error will be logged by setting IA32_RTIT_STATUS.Error, thereby disabling tracing when the problematic ToPA entry is reached (when proc_trace_table_offset points to the entry containing the error). Any packet bytes that are internally buffered when the error is detected may be lost.

Note that operational errors may also be signaled due to attempts to access restricted memory. See Section 36.2.4.4 for details.

A tracing software have a range of flexibility using ToPA to manage the interaction of Intel PT with application buffers, see Section 36.5.

36.2.4.3 Trace Transport Subsystem

When IA32_RTIT_CTL.FabricEn is set, the IA32_RTIT_CTL.ToPA bit is ignored, and trace output is written to the trace transport subsystem. The endpoints of this transport are platform-specific, and details of configuration options should refer to the specific platform documentation. The FabricEn bit is available to be set if CPUID(EAX=14H,ECX=0):EBX[bit 3] = 1.

36.2.4.4 Restricted Memory Access

Packet output cannot be directed to any regions of memory that are restricted by the platform. In particular, all memory accesses on behalf of packet output are checked against the SMRR regions. If there is any overlap with these regions, trace data collection will not function properly. Exact processor behavior is implementation-dependent; Table 36-5 summarizes several scenarios.

Table 36-5. Behavior on Restricted Memory Access

Scenario	Description
ToPA output region overlaps with SMRR	Stores to the restricted memory region will be dropped, and that packet data will be lost. Any attempt to read from that restricted region will return all 1s. The processor also may signal an error (Section 36.3.9) and disable tracing when the output pointer reaches the restricted region. If packet generation remains enabled, then packet output may continue once stores are no longer directed to restricted memory (on wrap, or if the output region is larger than the restricted memory region).
ToPA table overlaps with SMRR	The processor will signal an error (Section 36.3.9) and disable tracing when the ToPA read pointer (IA32_RTIT_OUTPUT_BASE + (proc_trace_table_offset « 3)) enters the restricted region.

It should also be noted that packet output should not be routed to the 4KB APIC MMIO region, as defined by the IA32_APIC_BASE MSR. For details about the APIC, refer to *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3A*. No error is signaled for this case.

Modifications to Restricted Memory Regions

It is recommended that software disable packet generation before modifying the SMRRs to change the scope of the SMRR regions. This is because the processor reserves the right to cache any number of ToPA table entries internally, after checking them against restricted memory ranges. Once cached, the entries will not be checked again, meaning one could potentially route packet output to a newly restricted region. Software can ensure that any cached entries are written to memory by clearing IA32_RTIT_CTL.TraceEn.

36.2.5 Enabling and Configuration MSRs

36.2.5.1 General Considerations

Trace packet generation is enabled and configured by a collection of model-specific registers (MSRs), which are detailed below. Some notes on the configuration MSR behavior:

- If Intel Processor Trace is not supported by the processor (see Section 36.3.1), RDMSR or WRMSR of the IA32_RTIT_* MSRs will cause #GP.
- A WRMSR to any of these configuration MSRs that begins and ends with IA32_RTIT_CTL.TraceEn set will #GP fault. Packet generation must be disabled before the configuration MSRs can be changed.

  Note: Software may write the same value back to IA32_RTIT_CTL without #GP, even if TraceEn=1.
- All configuration MSRs for Intel PT are duplicated per logical processor
- For each configuration MSR, any MSR write that attempts to change bits marked reserved, or utilize encodings marked reserved, will cause a #GP fault.
- All configuration MSRs for Intel PT are cleared on a cold RESET.
  - If CPUID.(EAX=14H, ECX=0):EBX.IPFILT_WRSTPRSV[bit 2] = 1, only the TraceEn bit is cleared on warm RESET; though this may have the impact of clearing other bits in IA32_RTIT_STATUS. Other MSR values of the trace configuration MSRs are preserved on warm RESET.
- The semantics of MSR writes to trace configuration MSRs in this chapter generally apply to explicit WRMSR to these registers, using VM-exit or VM-entry MSR load list to these MSRs, XRSTORS with requested feature bit map including XSAVE map component of state_8 (corresponding to IA32_XSS[bit 8]), and the write to IA32_RTIT_CTL.TraceEn by XSAVES (Section 36.3.5.2).

36.2.5.2 IA32_RTIT_CTL MSR

IA32_RTIT_CTL, at address 570H, is the primary enable and control MSR for trace packet generation. Bit positions are listed in Table 36-6.

Table 36-6. IA32_RTIT_CTL MSR

Position	Bit Name	At Reset	Bit Description
0	TraceEn	0	If 1, enables tracing; else tracing is disabled if 0. When this bit transitions from 1 to 0, all buffered packets are flushed out of internal buffers. A further store, fence, or architecturally serializing instruction may be required to ensure that packet data can be observed at the trace endpoint. See Section 36.2.5.3 for details of enabling and disabling packet generation. Note that the processor will clear this bit on #SMI (Section) and warm reset. Other MSR bits of IA32_RTIT_CTL (and other trace configuration MSRs) are not impacted by these events.
1	CYCEn	0	0: Disables CYC Packet (see Section 36.4.2.14). 1: Enables CYC Packet. This bit is reserved if CPUID.(EAX=14H, ECX=0):EBX.CPSB_CAM[bit 1] = 0.
2	OS	0	0: Packet generation is disabled when CPL = 0. 1: Packet generation may be enabled when CPL = 0.
3	User	0	0: Packet generation is disabled when CPL > 0. 1: Packet generation may be enabled when CPL > 0.
5:4	Reserved	0	Must be 0.
6	FabricEn	0	0: Trace output is directed to the memory subsystem, mechanism depends on IA32_RTIT_CTL.ToPA. 1: Trace output is directed to the trace transport subsystem, IA32_RTIT_CTL.ToPA is ignored. This bit is reserved if CPUID.(EAX=14H, ECX=0):ECX[bit 3] = 0.
7	CR3Filter	0	0: Disables CR3 filtering. 1: Enables CR3 filtering.
8	ToPA	0	0: Single-range output scheme enabled if CPUID.(EAX=14H, ECX=0):ECX.SNGLRGNOUT[bit 2] = 1 and IA32_RTIT_CTL.FabricEn=0. 1: ToPA output scheme enabled (see Section 36.2.4.2) if CPUID.(EAX=14H, ECX=0):ECX.TOPA[bit 0] = 1, and IA32_RTIT_CTL.FabricEn=0. Note: WRMSR to IA32_RTIT_CTL that sets TraceEn but clears this bit and FabricEn would cause #GP, if CPUID.(EAX=14H, ECX=0):ECX.SNGLRGNOUT[bit 2] = 0. WRMSR to IA32_RTIT_CTL that sets this bit causes #GP, if CPUID.(EAX=14H, ECX=0):ECX.TOPA[bit 0] = 0.
9	MTCEn	0	0: Disables MTC Packet (see Section 36.4.2.16). 1: Enables MTC Packet. This bit is reserved if CPUID.(EAX=14H, ECX=0):EBX.MTC[bit 3] = 0.
10	TSCEn	0	0: Disable TSC packets. 1: Enable TSC packets (see Section 36.4.2.11).
11	DisRETC	0	0: Enable RET compression. 1: Disable RET compression (see Section 36.2.1.2).
12	Reserved	0	Must be 0.
13	BranchEn	0	0: Disable COFI-based packets. 1: Enable COFI-based packets: FUP, TIP, TIP.PGE, TIP.PGD, TNT, MODE.Exec, MODE.TSX. see Section 36.2.4 for details on BranchEn.

Table 36-6. IA32_RTIT_CTL MSR

Position	Bit Name	At Reset	Bit Description
17:14	MTCFreq	0	Defines MTC packet Frequency, which is based on the core crystal clock, or Always Running Timer (ART). MTC will be sent each time the selected ART bit toggles. The following Encodings are defined: 0: ART(0), 1: ART(1), 2: ART(2), 3: ART(3), 4: ART(4), 5: ART(5), 6: ART(6), 7: ART(7), 8: ART(8), 9: ART(9), 10: ART(10), 11: ART(11), 12: ART(12), 13: ART(13), 14: ART(14), 15: ART(15) Software must use CPUID to query the supported encodings in the processor, see Section 36.3.1. Use of unsupported encodings will result in a #GP fault. This field is reserved if CPUID.(EAX=14H, ECX=0):EBX.MTC[bit 3] = 0.
18	Reserved	0	Must be 0.
22:19	CycThresh	0	CYC packet threshold, see Section 36.3.6 for details. CYC packets will be sent with the first eligible packet after N cycles have passed since the last CYC packet. If CycThresh is 0 then N=0, otherwise N is defined as $2^{(CycThresh-1)}$. The following Encodings are defined: 0: 0, 1: 1, 2: 2, 3: 4, 4: 8, 5: 16, 6: 32, 7: 64, 8: 128, 9: 256, 10: 512, 11: 1024, 12: 2048, 13: 4096, 14: 8192, 15: 16384 Software must use CPUID to query the supported encodings in the processor, see Section 36.3.1. Use of unsupported encodings will result in a #GP fault. This field is reserved if CPUID.(EAX=14H, ECX=0):EBX.CPSB_CAM[bit 1] = 0.
23	Reserved	0	Must be 0.
27:24	PSBFreq	0	Indicates the frequency of PSB packets. PSB packet frequency is based on the number of Intel PT packet bytes output, so this field allows the user to determine the increment of IA32_IA32_RTIT_STATUS.PacketByteCnt that should cause a PSB to be generated. Note that PSB insertion is not precise, but the average output bytes per PSB should approximate the SW selected period. The following Encodings are defined: 0: 2K, 1: 4K, 2: 8K, 3: 16K, 4: 32K, 5: 64K, 6: 128K, 7: 256K, 8: 512K, 9: 1M, 10: 2M, 11: 4M, 12: 8M, 13: 16M, 14: 32M, 15: 64M Software must use CPUID to query the supported encodings in the processor, see Section 36.3.1. Use of unsupported encodings will result in a #GP fault. This field is reserved if CPUID.(EAX=14H, ECX=0):EBX.CPSB_CAM[bit 1] = 0.
31:28	Reserved	0	Must be 0.
35:32	ADDR0_CFG	0	Configures the base/limit register pair IA32_RTIT_ADDR0_A/B based on the following encodings: 0: ADDR0 range unused. 1: The [IA32_RTIT_ADDR0_A..IA32_RTIT_ADDR0_B] range defines a FilterEn range. FilterEn will only be set when the IP is within this range, though other FilterEn ranges can additionally be used. See Section 36.2.2.3 for details on IP filtering. 2: The [IA32_RTIT_ADDR0_A..IA32_RTIT_ADDR0_B] range defines a TraceStop range. TraceStop will be asserted if code branches into this range. See 4.2.8 for details on TraceStop. 3..15: Reserved (#GP). This field is reserved if CPUID.(EAX=14H, ECX=1):EBX.RANGECNT[2:0] >= 0.

Table 36-6. IA32_RTIT_CTL MSR

Position	Bit Name	At Reset	Bit Description
39:36	ADDR1_CFG	0	Configures the base/limit register pair IA32_RTIT_ADDR1_A/B based on the following encodings: 0: ADDR1 range unused. 1: The [IA32_RTIT_ADDR1_A..IA32_RTIT_ADDR1_B] range defines a FilterEn range. FilterEn will only be set when the IP is within this range, though other FilterEn ranges can additionally be used. See Section 36.2.2.3 for details on IP filtering. 2: The [IA32_RTIT_ADDR1_A..IA32_RTIT_ADDR1_B] range defines a TraceStop range. TraceStop will be asserted if code branches into this range. See Section 36.4.2.10 for details on TraceStop. 3..15: Reserved (#GP). This field is reserved if CPUID.(EAX=14H, ECX=1):EBX.RANGECNT[2:0] < 2.
43:40	ADDR2_CFG	0	Configures the base/limit register pair IA32_RTIT_ADDR2_A/B based on the following encodings: 0: ADDR2 range unused. 1: The [IA32_RTIT_ADDR2_A..IA32_RTIT_ADDR2_B] range defines a FilterEn range. FilterEn will only be set when the IP is within this range, though other FilterEn ranges can additionally be used. See Section 36.2.2.3 for details on IP filtering. 2: The [IA32_RTIT_ADDR2_A..IA32_RTIT_ADDR2_B] range defines a TraceStop range. TraceStop will be asserted if code branches into this range. See Section 36.4.2.10 for details on TraceStop. 3..15: Reserved (#GP). This field is reserved if CPUID.(EAX=14H, ECX=1):EBX.RANGECNT[2:0] < 3.
47:44	ADDR3_CFG	0	Configures the base/limit register pair IA32_RTIT_ADDR3_A/B based on the following encodings: 0: ADDR3 range unused. 1: The [IA32_RTIT_ADDR3_A..IA32_RTIT_ADDR3_B] range defines a FilterEn range. FilterEn will only be set when the IP is within this range, though other FilterEn ranges can additionally be used. See Section 36.2.2.3 for details on IP filtering. 2: The [IA32_RTIT_ADDR3_A..IA32_RTIT_ADDR3_B] range defines a TraceStop range. TraceStop will be asserted if code branches into this range. See Section 36.4.2.10 for details on TraceStop. 3..15: Reserved (#GP). This field is reserved if CPUID.(EAX=14H, ECX=1):EBX.RANGECNT[2:0] < 4.
59:48	Reserved	0	Reserved only for future trace content enables, or address filtering configuration enables. Must be 0.
63:60	Reserved	0	Must be 0.

36.2.5.3 Enabling and Disabling Packet Generation with TraceEn

When TraceEn transitions from 0 to 1, Intel Processor Trace is enabled, and a series of packets may be generated. These packets help ensure that the decoder is aware of the state of the processor when the trace begins, and that it can keep track of any timing or state changes that may have occurred while packet generation was disabled. A full PSB+ (see Section 36.4.2.17) will be generated if IA32_RTIT_STATUS.PacketByteCnt=0, and may be generated in other cases as well. Otherwise, timing packets will be generated, including TSC, TMA, and CBR (see Section 36.4.2).

In addition to the packets discussed above, if and when PacketEn (Section 36.2.3.1) transitions from 0 to 1 (which may happen immediately, depending on filtering settings), a TIP.PGE packet (Section 36.4.2.3) will be generated.

When TraceEn is set, the processor may read ToPA entries from memory and cache them internally. For this reason, software should disable packet generation before making modifications to the ToPA tables (or changing the config-

uration of restricted memory regions). See Section 36.7 for more details of packets that may be generated with modifications to TraceEn.

Disabling Packet Generation

Clearing TraceEn causes any packet data buffered within the logical processor to be flushed out, after which the output MSRs (IA32_RTIT_OUTPUT_BASE and IA32_RTIT_OUTPUT_MASK_PTRS) will have stable values. When output is directed to memory, a store, fence, or architecturally serializing instruction may be required to ensure that the packet data is globally observed. No special packets are generated by disabling packet generation, though a TIP.PGD may result if PacketEn=1 at the time of disable.

Other Writes to IA32_RTIT_CTL

Any attempt to modify IA32_RTIT_CTL while TraceEn is set will result in a general-protection fault (#GP) unless the same write also clears TraceEn. However, writes to IA32_RTIT_CTL that do not modify any bits will not cause a #GP, even if TraceEn remains set.

36.2.5.4 IA32_RTIT_STATUS MSR

The IA32_RTIT_STATUS MSR is readable and writable by software, but some bits (ContextEn, TriggerEn) are read-only and cannot be directly modified. The WRMSR instruction ignores these bits in the source operand (attempts to modify these bits are ignored and do not cause WRMSR to fault).

This MSR can only be written when IA32_RTIT_CTL.TraceEn is 0; otherwise WRMSR causes a general-protection fault (#GP). The processor does not modify the value of this MSR while TraceEn is 0 (software can modify it with WRMSR).

Table 36-7. IA32_RTIT_STATUS MSR

Position	Bit Name	At Reset	Bit Description
0	FilterEn	0	This bit is written by the processor, and indicates that tracing is allowed for the current IP, see Section 36.2.3.5. Writes are ignored.
1	ContextEn	0	The processor sets this bit to indicate that tracing is allowed for the current context. See Section 36.2.3.3. Writes are ignored.
2	TriggerEn	0	The processor sets this bit to indicate that tracing is enabled. See Section 36.2.3.2. Writes are ignored.
3	Reserved	0	Must be 0.
4	Error	0	The processor sets this bit to indicate that an operational error has been encountered. When this bit is set, TriggerEn is cleared to 0 and packet generation is disabled. For details, see "ToPA Errors" in Section 36.2.4.2. When TraceEn is cleared, software can write this bit. Once it is set, only software can clear it. It is not recommended that software ever set this bit, except in cases where it is restoring a prior saved state.
5	Stopped	0	The processor sets this bit to indicate that a ToPA Stop condition has been encountered. When this bit is set, TriggerEn is cleared to 0 and packet generation is disabled. For details, see "ToPA STOP" in Section 36.2.4.2. When TraceEn is cleared, software can write this bit. Once it is set, only software can clear it. It is not recommended that software ever set this bit, except in cases where it is restoring a prior saved state.
31:6	Reserved	0	Must be 0.
48:32	PacketByteCnt	0	This field is written by the processor, and holds a count of packet bytes that have been sent out. The processor also uses this field to determine when the next PSB packet should be inserted. Note that the processor may clear or modify this field at any time while IA32_RTIT_CTL.TraceEn=1. It will have a stable value when IA32_RTIT_CTL.TraceEn=0. See Section 36.4.2.17 for details.
63:49	Reserved	0	Must be 0.

36.2.5.5 IA32_RTIT_ADDRn_A and IA32_RTIT_ADDRn_B MSRs

The role of the IA32_RTIT_ADDRn_A/B register pairs, for each n, is determined by the corresponding ADDRn_CFG fields in IA32_RTIT_CTL (see Section 36.2.5.2). The number of these register pairs is enumerated by CPUID.(EAX=14H, ECX=1):EAX.RANGECNT[2:0].

- Processors that enumerate support for 1 range support:

  IA32_RTIT_ADDR0_A, IA32_RTIT_ADDR0_B
- Processors that enumerate support for 2 ranges support:

  IA32_RTIT_ADDR0_A, IA32_RTIT_ADDR0_B

  IA32_RTIT_ADDR1_A, IA32_RTIT_ADDR1_B
- Processors that enumerate support for 3 ranges support:

  IA32_RTIT_ADDR0_A, IA32_RTIT_ADDR0_B

  IA32_RTIT_ADDR1_A, IA32_RTIT_ADDR1_B

  IA32_RTIT_ADDR2_A, IA32_RTIT_ADDR2_B
- Processors that enumerate support for 4 ranges support:

  IA32_RTIT_ADDR0_A, IA32_RTIT_ADDR0_B

  IA32_RTIT_ADDR1_A, IA32_RTIT_ADDR1_B

  IA32_RTIT_ADDR2_A, IA32_RTIT_ADDR2_B

  IA32_RTIT_ADDR3_A, IA32_RTIT_ADDR3_B

Each register has a single 64-bit field that holds a linear address value. Writes must ensure that the address is properly sign-extended, otherwise a #GP fault will result.

36.2.5.6 IA32_RTIT_CR3_MATCH MSR

The IA32_RTIT_CR3_MATCH register is compared against CR3 when IA32_RTIT_CTL.CR3Filter is 1. Bits 63:5 hold the CR3 address value to match, bits 4:0 are reserved to 0. For more details on CR3 filtering and the treatment of this register, see Section 36.2.2.2.

This MSR can be written only when IA32_RTIT_CTL.TraceEn is 0; otherwise WRMSR causes a general-protection fault (#GP). IA32_RTIT_CR3_MATCH[4:0] are reserved and must be 0; an attempt to set those bits using WRMSR causes a #GP.

36.2.5.7 IA32_RTIT_OUTPUT_BASE MSR

This MSR is used to configure the trace output destination, when output is directed to memory (IA32_RTIT_CTL.FabricEn = 0). The size of the address field is determined by the maximum physical address width (MAXPHYADDR), as reported by CPUID.80000008H:EAX[7:0].

When the ToPA output scheme is used, the processor may update this MSR when packet generation is enabled, and those updates are asynchronous to instruction execution. Therefore, the values in this MSR should be considered unreliable unless packet generation is disabled (IA32_RTIT_CTL.TraceEn = 0).

Accesses to this MSR are supported only if Intel PT output to memory is supported, hence when either CPUID.(EAX=14H, ECX=0):ECX[bit 0] or CPUID.(EAX=14H, ECX=0):ECX[bit 2] are set. Otherwise WRMSR or RDMSR cause a general-protection fault (#GP). If supported, this MSR can be written only when IA32_RTIT_CTL.TraceEn is 0; otherwise WRMSR causes a general-protection fault (#GP).

Table 36-8. IA32_RTIT_OUTPUT_BASE MSR

Position	Bit Name	At Reset	Bit Description
6:0	Reserved	0	Must be 0.

Table 36-8. IA32_RTIT_OUTPUT_BASE MSR

Position	Bit Name	At Reset	Bit Description
MAXPHYADDR-1:7	BasePhysAddr	0	The base physical address. How this address is used depends on the value of IA32_RTIT_CTL.ToPA: 0: This is the base physical address of a single, contiguous physical output region. This could be mapped to DRAM or to MMIO, depending on the value. The base address should be aligned with the size of the region, such that none of the 1s in the mask value(Section 36.2.5.8) overlap with 1s in the base address. If the base is not aligned, an operational error will result (see Section 36.3.9). 1: The base physical address of the current ToPA table. The address must be 4K aligned. Writing an address in which bits 11:7 are non-zero will not cause a #GP, but an operational error will be signaled once TraceEn is set. See "ToPA Errors" in Section 36.2.4.2 as well as Section 36.3.9.
63:MAXPHYADDR	Reserved	0	Must be 0.

36.2.5.8 IA32_RTIT_OUTPUT_MASK_PTRS MSR

This MSR holds any mask or pointer values needed to indicate where the next byte of trace output should be written. The meaning of the values held in this MSR depend on whether the ToPA output mechanism is in use. See Section 36.2.4.2 for details.

The processor updates this MSR while when packet generation is enabled, and those updates are asynchronous to instruction execution. Therefore, the values in this MSR should be considered unreliable unless packet generation is disabled (IA32_RTIT_CTL.TraceEn = 0).

Accesses to this MSR are supported only if Intel PT output to memory is supported, hence when either CPUID.(EAX=14H, ECX=0):ECX[bit 0] or CPUID.(EAX=14H, ECX=0):ECX[bit 2] are set. Otherwise WRMSR or RDMSR cause a general-protection fault (#GP). If supported, this MSR can be written only when IA32_RTIT_CTL.TraceEn is 0; otherwise WRMSR causes a general-protection fault (#GP).

Table 36-9. IA32_RTIT_OUTPUT_MASK_PTRS MSR

Position	Bit Name	At Reset	Bit Description
6:0	LowerMask	7FH	Forced to 1, writes are ignored.
31:7	MaskOrTableOffset	0	The use of this field depends on the value of IA32_RTIT_CTL.ToPA: 0: This field holds bits 31:7 of the mask value for the single, contiguous physical output region. The size of this field indicates that regions can be of size 128B up to 4GB. This value (combined with the lower 7 bits, which are reserved to 1) will be ANDed with the OutputOffset field to determine the next write address. All 1s in this field should be consecutive and starting at bit 7, otherwise the region will not be contiguous, and an operational error (Section 36.3.9) will be signaled when TraceEn is set. 1: This field holds bits 27:3 of the offset pointer into the current ToPA table. This value can be added to the IA32_RTIT_OUTPUT_BASE value to produce a pointer to the current ToPA table entry, which itself is a pointer to the current output region. In this scenario, the lower 7 reserved bits are ignored. This field supports tables up to 256 MBytes in size.
63:32	OutputOffset	0	The use of this field depends on the value of IA32_RTIT_CTL.ToPA: 0: This is bits 31:0 of the offset pointer into the single, contiguous physical output region. This value will be added to the IA32_RTIT_OUTPUT_BASE value to form the physical address at which the next byte of packet output data will be written. This value must be less than or equal to the MaskOrTableOffset field, otherwise an operational error (Section 36.3.9) will be signaled when TraceEn is set. 1: This field holds bits 31:0 of the offset pointer into the current ToPA output region. This value will be added to the output region base field, found in the current ToPA table entry, to form the physical address at which the next byte of trace output data will be written. This value must be less than the ToPA entry size, otherwise an operational error (Section 36.3.9) will be signaled when TraceEn is set.

36.2.6 Interaction of Intel® Processor Trace and Other Processor Features

36.2.6.1 Intel® Transactional Synchronization Extensions (Intel® TSX)

The operation of Intel TSX is described in Chapter 14 of the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 1*. For tracing purpose, packet generation does not distinguish between hardware lock elision (HLE) and restricted transactional memory (RTM), but speculative execution does have impacts on the trace output. Specifically, packets are generated as instructions complete, even for instructions in a transactional region that is later aborted. For this reason, debugging software will need indication of the beginning and end of a transactional region; this will allow software to understand when instructions are part of a transactional region and whether that region has been committed.

To enable this, TSX information is included in a MODE packet leaf. The mode bits in the leaf are:

- **InTX**: Set to 1 on an TSX transaction begin, and cleared on transaction commit or abort.
- **TXAbort**: Set to 1 only when InTX transitions from 1 to 0 on an abort. Cleared otherwise.

If BranchEn=1, this MODE packet will be sent each time the transaction status changes. See Table 36-10 for details.

Table 36-10. TSX Packet Scenarios

TSX Event	Instruction	Packets
Transaction Begin	Either XBEGIN or XACQUIRE lock (the latter if executed transactionally)	MODE(TXAbort=0, InTX=1), FUP(CurrentIP)
Transaction Commit	Either XEND or XRELEASE lock, if transactional execution ends. This happens only on the outermost commit	MODE(TXAbort=0, InTX=0), FUP(CurrentIP)
Transaction Abort	XABORT or other transactional abort	MODE(TXAbort=1, InTX=0), FUP(CurrentIP), TIP(TargetIP)
Other	One of the following: ▪ Nested XBEGIN or XACQUIRE lock ▪ An outer XACQUIRE lock that doesn't begin a transaction (InTX not set) ▪ Non-outermost XEND or XRELEASE lock	None. No change to TSX mode bits for these cases.

The CurrentIP listed above is the IP of the associated instruction. The TargetIP is the IP of the next instruction to be executed; for HLE, this is the XACQUIRE lock; for RTM, this is the fallback handler.

Intel PT stores are non-transactional, and thus packet writes are not rolled back on TSX abort.

TSX and IP Filtering

A complication with tracking transactions is handling transactions that start or end outside of the tracing region. Transactions can't span across a change in ContextEn, because CPL changes and CR3 changes each cause aborts. But a transaction can start within the IP filter region and end outside it.

To assist the decoder handling this situation, MODE.TSX packets can be sent even if FilterEn=0, though there will be no FUP attached. Instead, they will merely serve to indicate to the decoder when transactions are active and when they are not. When tracing resumes (due to PacketEn=1), the last MODE.TSX preceding the TIP.PGE will indicate the current transaction status.

System Management Mode (SMM)

SMM code has special privileges that non-SMM code does not have. Intel Processor Trace can be used to trace SMM code, but special care is taken to ensure that SMM handler context is not exposed in any non-SMM trace collection. Additionally, packet output from tracing non-SMM code cannot be written into memory space that is either protected by SMRR or used by the SMM handler.

SMM is entered via a system management interrupt (SMI). SMI delivery saves the value of IA32_RTIT_CTL.TraceEn into SMRAM and then clears it, thereby disabling packet generation.

The saving and clearing of IA32_RTIT_CTL.TraceEn ensures two things:

1. All internally buffered packet data is flushed before entering SMM (see Section 36.2.5.2).
2. Packet generation ceases before entering SMM, so any tracing that was configured outside SMM does not continue into SMM. No SMM instruction pointers or other state will be exposed in the non-SMM trace.

When the RSM instruction is executed to return from SMM, the TraceEn value that was saved by SMI delivery is restored, allowing tracing to be resumed. As is done any time packet generation is enabled, ContextEn is re-evaluated, based on the values of CPL, CR3, etc., established by RSM.

Like other interrupts, delivery of an SMI produces a FUP containing the IP of the next instruction to execute. By toggling TraceEn, SMI and RSM can produce TIP.PGD and TIP.PGE packets, respectively, indicating that tracing was disabled or re-enabled. See Table 36.7 for more information about packets entering and leaving SMM.

Although #SMI and RSM change CR3, PIP packets are not generated in these cases. With #SMI tracing is disabled before the CR3 change; with RSM TraceEn is restored after CR3 is written.

TraceEn must be cleared before executing RSM, otherwise it will cause a shutdown. Further, on processors that restrict use of Intel PT with LBRs (see Section 36.3.1.2), any RSM that results in enabling of both will cause a shutdown.

Intel PT can support tracing of System Transfer Monitor operating in SMM, see Section 36.6.

36.2.6.2 Virtual-Machine Extensions (VMX)

Initial implementations of Intel Processor Trace do not support tracing in VMX operation. This is indicated by IA32_VMX_MISC[bit 14] returns 0. Execution of the VMXON instruction clears TraceEn. An attempt to set IA32_RTIT_CTL.TraceEn using WRMSR in VMX operation causes a general-protection fault (#GP).

For processors that Intel Processor Trace supports tracing in VMX operation, IA32_VMX_MISC[bit 14] reports 1 if TraceEn can be set post-VMXON. Details of tracing post-VMXON is described in Section 36.5.

36.2.6.3 Intel Software Guard Extensions (SGX)

SGX provides an application with ability to instantiate a protective container (an enclave) with confidentiality and integrity (see *Intel® Software Guard Extensions Programming Reference*). On a processor with both Intel PT and SGX enabled, when executing code within a production enclave, no control flow packets are produced by Intel PT. Enclave entry will clear ContextEn, thereby blocking control flow packet generation. A TIP.PGD packet will be generated if PacketEn=1 at the time of the entry.

Upon enclave exit, ContextEn will no longer be forced to 0. If other enables are set at the time, a TIP.PGE may be generated to indicate that tracing is resumed.

During the enclave execution, Intel PT remains enabled, and periodic or timing packets such as PSB, TSC, MTC, or CBR can still be generated. No IPs or other architectural state will be exposed.

For packet generation examples on enclave entry or exit, see Section 36.7.

Debug Enclaves

SGX allows an enclave to be configured with relaxed protection of confidentiality for debug purposes, see *Intel® Software Guard Extensions Programming Reference*. In a debug enclave, Intel PT continues to function normally. Specifically, ContextEn is not impacted by enclave entry or exit. Hence the generation of ContextEn-dependent packets within a debug enclave is allowed.

36.2.6.4 SENTER/ENTERACCS and ACM

GETSEC[SENTER] and GETSEC[ENTERACCS] instructions clear TraceEn, and it is not restored when those instruction complete. SENTER also causes TraceEn to be cleared on other logical processors when they rendezvous and enter the SENTER sleep state. In these two cases, the disabling of packet generation is not guaranteed to flush internally buffered packets. Some packets may be dropped.

When executing an authenticated code module (ACM), packet generation is silently disabled during ACRAM setup. TraceEn will be cleared, but no TIP.PGD packet is generated. After completion of the module, the TraceEn value will be restored. There will be no TIP.PGE packet, but timing packets, like TSC and CBR, may be produced.

36.2.6.5 Intel® Memory Protection Extensions (Intel® MPX)

Bounds exceptions (#BR) caused by Intel MPX are treated like other exceptions, producing FUP and TIP packets that indicate the source and destination IPs.

36.3 CONFIGURATION AND PROGRAMMING GUIDELINE

36.3.1 Detection of Intel Processor Trace and Capability Enumeration

Processor support for Intel Processor Trace is indicated by CPUID.(EAX=07H,ECX=0H):EBX[bit 25] = 1. CPUID function 14H is dedicated to enumerate the resource and capability of processors that report CPUID.(EAX=07H,ECX=0H):EBX[bit 25] = 1. Different processor generations may have architecturally-defined variation in capabilities. Table 36-11 describes details of the enumerable capabilities that software must use across generations of processors that support Intel Processor Trace.

Table 36-11. CPUID Leaf 14H Enumeration of Intel Processor Trace Capabilities

CPUID.(EAX=14H,ECX=0)		Name	Description Behavior
Register	Bits		
EAX	31:0	Maximum valid sub-leaf Index	Specifies the index of the maximum valid sub-leaf for this CPUID leaf
EBX	0	CR3 Filtering Support	1: Indicates that IA32_RTIT_CTL.CR3Filter can be set to 1, and that IA32_RTIT_CR3_MATCH MSR can be accessed. See Section 36.2.5. 0: Indicates that writes that set IA32_RTIT_CTL.CR3Filter to 1, or any access to IA32_RTIT_CR3_MATCH, will #GP fault.
	1	Configurable PSB and Cycle-Accurate Mode Supported	1: (a) IA32_RTIT_CTL.PSBFreq can be set to a non-zero value, in order to select the preferred PSB frequency (see below for allowed values). (b) IA32_RTIT_STATUS.PacketByteCnt can be set to a non-zero value, and will be incremented by the processor when tracing to indicate progress towards the next PSB. If trace packet generation is enabled by setting TraceEn, a PSB will only be generated if PacketByteCnt=0. (c) IA32_RTIT_CTL.CYCEn can be set to 1 to enable Cycle-Accurate Mode. See Section 36.2.5. 0: (a) Any attempt to set IA32_RTIT_CTL.PSBFreq, to set IA32_RTIT_CTL.CYCEn, or write a non-zero value to IA32_RTIT_STATUS.PacketByteCnt any access to IA32_RTIT_CR3_MATCH, will #GP fault. (b) If trace packet generation is enabled by setting TraceEn, a PSB is always generated. (c) Any attempt to set IA32_RTIT_CTL.CYCEn will #GP fault.
	2	IP Filtering and TraceStop supported, and Preserve Intel PT MSRs across warm reset	1: (a) IA32_RTIT_CTL provides at one or more ADDRn_CFG field to configure the corresponding address range MSRs for IP Filtering or IP TraceStop. Each ADDRn_CFG field accepts a value in the range of 0:2 inclusive. The number of ADDRn_CFG fields is reported by CPUID.(EAX=14H, ECX=1):EAX.RANGECNT[2:0]. (b) At least one register pair IA32_RTIT_ADDRn_A and IA32_RTIT_ADDRn_B are provided to configure address ranges for IP filtering or IP TraceStop. (c) On warm reset, all Intel PT MSRs will retain their pre-reset values, though IA32_RTIT_CTL.TraceEn will be cleared. The Intel PT MSRs are listed in Section 36.2.5. 0: (a) An Attempt to write IA32_RTIT_CTL.ADDRn_CFG with non-zero encoding values will cause #GP. (b) Any access to IA32_RTIT_ADDRn_A and IA32_RTIT_ADDRn_B, will #GP fault. (c) On warm reset, all Intel PT MSRs will be cleared.

Table 36-11. CPUID Leaf 14H Enumeration of Intel Processor Trace Capabilities

CPUID.(EAX=14H,ECX=0)		Name	Description Behavior
Register	Bits		
	3	MTC Supported	1: IA32_RTIT_CTL.MTCEn can be set to 1, and MTC packets will be generated. See Section 36.2.5. 0: An attempt to set IA32_RTIT_CTL.MTCEn or IA32_RTIT_CTL.MTCFreq to a non-zero value will #GP fault.
	31:4	Reserved	
ECX	0	ToPA Output Supported	1: Tracing can be enabled with IA32_RTIT_CTL.ToPA = 1, hence utilizing the ToPA output scheme (Section 36.2.4.2) IA32_RTIT_OUTPUT_BASE and IA32_RTIT_OUTPUT_MASK_PTRS MSRs can be accessed. 0: Unless CPUID.(EAX=14H, ECX=0):ECX.SNGLRNGOUT[bit 2] = 1. writes to IA32_RTIT_OUTPUT_BASE or IA32_RTIT_OUTPUT_MASK_PTRS. MSRs will #GP fault.
	1	ToPA Tables Allow Multiple Output Entries	1: ToPA tables can hold any number of output entries, up to the maximum allowed by the MaskOrTableOffset field of IA32_RTIT_OUTPUT_MASK_PTRS. 0: ToPA tables can hold only one output entry, which must be followed by an END=1 entry which points back to the base of the table. Further, ToPA PMIs will be delivered before the region is filled. See ToPA PMI in Section 36.2.4.2. If there is more than one output entry before the END entry, or if the END entry has the wrong base address, an operational error will be signaled (see "ToPA Errors" in Section 36.2.4.2).
	2	Single-Range Output Supported	1: Enabling tracing (TraceEn=1) with IA32_RTIT_CTL.ToPA=0 is supported. 0: Unless CPUID.(EAX=14H, ECX=0):ECX.TOPAOUT[bit 0] = 1. writes to IA32_RTIT_OUTPUT_BASE or IA32_RTIT_OUTPUT_MASK_PTRS. MSRs will #GP fault.
	3	Output to Trace Transport Subsystem Supported	1: Setting IA32_RTIT_CTL.FabricEn to 1 is supported. 0: IA32_RTIT_CTL.FabricEn is reserved. Write 1 to IA32_RTIT_CTL.FabricEn will #GP fault.
	30:4	Reserved	
	31	IP Payloads are LIP	1: Generated packets which contain IP payloads have LIP values, which include the CS base component. 0: Generated packets which contain IP payloads have RIP values, which are the offset from CS base.
EDX	31:0	Reserved	

If CPUID.(EAX=14H, ECX=0):EAX reports a non-zero value, additional capabilities of Intel Processor Trace are described in the sub-leaves of CPUID leaf 14H.

Table 36-12. CPUID Leaf 14H, sub-leaf 1H Enumeration of Intel Processor Trace Capabilities

CPUID.(EAX=14H,ECX=1)		Name	Description Behavior
Register	Bits		
EAX	2:0	Number of Address Ranges	A non-zero value specifies the number ADDRn_CFG field supported in IA32_RTIT_CTL and the number of register pair IA32_RTIT_ADDRn_A/IA32_RTIT_ADDRn_B supported for IP filtering and IP TraceStop. **NOTE:** Currently, no processors support more than 4 address ranges.
	15:3	Reserved	
	31:16	Bitmap of supported MTC Period Encodings	The non-zero bit positions indicate the map of supported encoding values for the IA32_RTIT_CTL.MTCFreq field. This applies only if CPUID.(EAX=14H, ECX=0):EBX.MTC[bit 3] = 1 (MTC Packet generation is supported), otherwise the MTCFreq field is reserved to 0. Each bit position in this field represents 1 encoding value in the 4-bit MTCFreq field (ie, bit 0 is associated with encoding value 0). For each bit: 1: MTCFreq can be assigned the associated encoding value. 0: MTCFreq cannot be assigned to the associated encoding value. A write to IA32_RTIT_CTLMTCFreq with unsupported encoding will cause #GP fault.
EBX	15:0	Bitmap of supported Cycle Threshold values	The non-zero bit positions indicate the map of supported encoding for the IA32_RTIT_CTL.CycThresh field. This applies only if CPUID.(EAX=14H, ECX=0):EBX.CPSB_CAM[bit 1] = 1 (Cycle-Accurate Mode is Supported), otherwise the CycThresh field is reserved to 0. See Section 36.2.5. Each bit position in this field represents 1 encoding value in the 4-bit CycThresh field (ie, bit 0 is associated with encoding value 0). For each bit: 1: CycThresh can be assigned the associated encoding value. 0: CycThresh cannot be assigned to the associated encoding value. A write to CycThresh with unsupported encoding will cause #GP fault.
	31:16	Bitmap of supported Configurable PSB Frequency encoding	The non-zero bit positions indicate the map of supported encoding for the IA32_RTIT_CTL.PSBFreq field. This applies only if CPUID.(EAX=14H, ECX=0):EBX.CPSB_CAM[bit 1] = 1 (Configurable PSB is supported), otherwise the PSBFreq field is reserved to 0. See Section 36.2.5. Each bit position in this field represents 1 encoding value in the 4-bit PSBFreq field (ie, bit 0 is associated with encoding value 0). For each bit: 1: PSBFreq can be assigned the associated encoding value. 0: PSBFreq cannot be assigned to the associated encoding value. A write to PSBFreq with unsupported encoding will cause #GP fault.
ECX	31:0	Reserved	
EDX	31:0	Reserved	

36.3.1.1 Packet Decoding of RIP versus LIP

FUP, TIP, TIP.PGE, and TIP.PGE packets can contain an instruction pointer (IP) payload. On some processor generations, this payload will be an effective address (RIP), while on others this will be a linear address (LIP). In the former case, the payload is the offset from the current CS base address, while in the latter it is the sum of the offset

and the CS base address (Note that in real mode, the CS base address is the value of CS<<4, while in protected mode the CS base address is the base linear address of the segment indicated by the CS register.). Which IP type is in use is indicated by enumeration (see CPUID.(EAX=14H, ECX=0):ECX.LIP[bit 31] in Table 36-11).

For software that executes while the CS base address is 0 (including all software executing in 64-bit mode), the difference is indistinguishable. A trace decoder must account for cases where the CS base address is not 0 and the resolved LIP will not be evident in a trace generated on a CPU that enumerates use of RIP. This is likely to cause problems when attempting to link the trace with the associated binaries.

Note that IP comparison logic, for IP filtering and TraceStop range calculation, is based on the same IP type as these IP packets. For processors that output RIP, the IP comparison mechanism is also based on RIP, and hence on those processors RIP values should be written to IA32_RTIT_ADDRn_[AB] MSRs. This can produce differing behavior if the same trace configuration setting is run on processors reporting different IP types, i.e. CPUID.(EAX=14H, ECX=0):ECX.LIP[bit 31]. Care should be taken to check CPUID when configuring IP filters.

36.3.1.2 Model Specific Capability Restrictions

Some processor generations impose restrictions that prevent use of LBRs/BTS/BTM/LERs when software has enabled tracing with Intel Processor Trace. On these processors, when TraceEn is set, updates of LBR, BTS, BTM, LERs are suspended but the states of the corresponding IA32_DEBUGCTL control fields remained unchanged as if it were still enabled. When TraceEn is cleared, the LBR array is reset, and LBR/BTS/BTM/LERs updates will resume. Further, reads of these registers will return 0, and writes will be dropped.

The list of MSRs whose updates/accesses are restricted follows.

- MSR_LASTBRANCH_x_TO_IP, MSR_LASTBRANCH_x_FROM_IP, MSR_LBR_INFO_x, MSR_LASTBRANCH_TOS
- MSR_LER_FROM_IP, MSR_LER_TO_IP
- MSR_LBR_SELECT

For processor with CPUID DisplayFamily_DisplayModel signature of 06_3DH, 06_47H, 06_4EH, 06_4FH, 06_56H and 06_5EH, the use of Intel PT and LBRs are mutually exclusive.

36.3.2 Enabling and Configuration of Trace Packet Generation

To configure trace packets, enable packet generation, and capture packets, software starts with using CPUID instruction to detect its feature flag, CPUID.(EAX=07H,ECX=0H):EBX[bit 25] = 1; followed by enumerating the capabilities described in Section 36.3.1.

Based on the capability queried from Section 36.3.1, software must configure a number of model-specific registers. This section describes programming considerations related to those MSRs.

36.3.2.1 Enabling Packet Generation

When configuring and enabling packet generation, the IA32_RTIT_CTL MSR should be written after any other Intel PT MSRs have been written, since writes to the other configuration MSRs cause a general-protection fault (#GP) if TraceEn = 1. If a prior trace collection context is not being restored, then software should first clear IA32_RTIT_STATUS. This is important since the Stopped, and Error fields are writable; clearing the MSR clears any values that may have persisted from prior trace packet collection contexts. See Section 36.2.5.2 for details of packets generated by setting TraceEn to 1.

If setting TraceEn to 1 causes an operational error (see Section 36.3.9), there may be a delay after the WRMSR completes before the error is signaled in the IA32_RTIT_STATUS MSR.

While packet generation is enabled, the values of some configuration MSRs (e.g., IA32_RTIT_STATUS and IA32_RTIT_OUTPUT_*) are transient, and reads may return values that are out of date. Only after packet generation is disabled (by clearing TraceEn) do reads of these MSRs return reliable values.

36.3.2.2 Disabling Packet Generation

After disabling packet generation by clearing IA32_RTIT_CTL, it is advisable to read the IA32_RTIT_STATUS MSR (Section 36.2.5.4):

- If the Error bit is set, an operational error was encountered, and the trace is most likely compromised. Software should check the source of the error (by examining the output MSR values), correct the source of the problem, and then attempt to gather the trace again. For details on operational errors, see Section 36.3.9. Software should clear IA32_RTIT_STATUS.Error before re-enabling packet generation.
- If the Stopped bit is set, software execution encountered an IP TraceStop (see Section 36.2.2.3) or the ToPA Stop condition (see "ToPA STOP" in Section 36.2.4.2) before packet generation was disabled.

36.3.3 Flushing Trace Output

Packets are first buffered internally and then written out asynchronously. To collect packet output for post-processing, a collector needs first to ensure that all packet data has been flushed from internal buffers. Software can ensure this by stopping packet generation by clearing IA32_RTIT_CTL.TraceEn (see "Disabling Packet Generation" in Section 36.2.5.2).

When software clears IA32_RTIT_CTL.TraceEn to flush out internally buffered packets, the logical processor issues an SFENCE operation which ensures that WC trace output stores will be ordered with respect to the next store, or serializing operation. A subsequent read from the same logical processor will see the flushed trace data, while a read from another logical processor should be preceded by a store, fence, or architecturally serializing operation on the tracing logical processor.

When the flush operations complete, the IA32_RTIT_OUTPUT_* MSR values indicate where the trace ended. While TraceEn is set, these MSRs may hold stale values.

36.3.4 Warm Reset

The MSRs software uses to program Intel Processor Trace are cleared after a power-on RESET (or cold RESET). On a warm RESET, the contents of those MSRs can retain their values from before the warm RESET with the exception that IA32_RTIT_CTL.TraceEn will be cleared (which may have the side effect of clearing some bits in IA32_RTIT_STATUS).

36.3.5 Context Switch Consideration

To facilitate construction of instruction execution traces at the granularity of a software process or thread context, software can save and restore the states of the trace configuration MSRs across the process or thread context switch boundary. The principle is the same as saving and restoring the typical architectural processor states across context switches.

36.3.5.1 Manual Trace Configuration Context Switch

The configuration can be saved and restored through a sequence of instructions of RDMSR, management of MSR content and WRMSR. To stop tracing and to ensure that all configuration MSRs contain stable values, software must clear IA32_RTIT_CTL.TraceEn before reading any other trace configuration MSRs. The recommended method for saving trace configuration context manually follows:

1. RDMSR IA32_RTIT_CTL, save value to memory
2. WRMSR IA32_RTIT_CTL with saved value from RDMSR above and TraceEn cleared
3. RDMSR all other configuration MSRs whose values had changed from previous saved value, save changed values to memory

When restoring the trace configuration context, IA32_RTIT_CTL should be restored last:

1. Read saved configuration MSR values, aside from IA32_RTIT_CTL, from memory, and restore them with WRMSR
2. Read saved IA32_RTIT_CTL value from memory, and restore with WRMSR.

36.3.5.2 Trace Configuration Context Switch Using XSAVES/XRSTORS

On processors whose XSAVE feature set supports XSAVES and XRSTORS, the Trace configuration state can be saved using XSAVES and restored by XRSTORS, in conjunction the bit field associated with supervisory state component in IA32_XSS. See Chapter 13, "Managing State Using the XSAVE Feature Set" of *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 1*.

CPUID leaf 0DH enumerates the capabilities of the XSAVE feature set. Within CPUID leaf 0DH, the sub-functions related to supervisor state management of the trace configuration MSRs are shown in Table 36-13 and Table 36-14.

Table 36-13. CPUID Leaf 0DH, sub-leaf 1H Enumeration of XSAVE Feature Set

CPUID.(EAX=0DH,ECX=1)		Name	Description Behavior
Register	Bit(s)		
ECX	8	Supervisory Trace Configuration State support in IA32_XSS	If 1, IA32_XSS[bit 8] is supported for supervisor state save/restor using XSAVES/XRSTORS for trace configuration MSR states. Otherwise, IA32_XSS[bit 8] is reserved.
EBX	31:0	Total size of the XSAVE area	Total size of the XSAVE area containing all states enabled by XCR0 | IA32_XSS.

Table 36-14. CPUID Leaf 0DH, sub-leaf 8H Enumeration of XSAVE Feature Set

CPUID.(EAX=0DH,ECX=8)		Name	Description Behavior
Register	Bit(s)		
EAX	31:0	Size of Trace Configuration State Save Area	The size in bytes of this component's save area in the XSAVE area (from the offset specified in EBX)
EBX	31:0	Offset of Trace Configuration State Save Area	The offset in bytes of this component's save area from the beginning of the XSAVE area.
ECX	0	Valid	If 1, sub leaf index is valid and maps to IA32_XSS[bit 8]. Otherwise, sub leaf index is invalid.

The layout of the trace configuration component state in the XSAVE area is shown in Table 36-15.

Table 36-15. Memory Layout of the Trace Configuration State Component

Offset within Component Area	Field	Offset within Component Area	Field
0H	IA32_RTIT_CTL	08H	IA32_RTIT_OUTPUT_BASE
10H	IA32_RTIT_OUTPUT_MASK_PTRS	18H	IA32_RTIT_STATUS
20H	IA32_RTIT_CR3_MATCH	28H	IA32_RTIT_ADDR0_A
30H	IA32_RTIT_ADDR0_B	38H	IA32_RTIT_ADDR1_A
40H	IA32_RTIT_ADDR1_B	48H	IA32_RTIT_ADDR2_A
50H	IA32_RTIT_ADDR2_B	58H	IA32_RTIT_ADDR3_A
60H	IA32_RTIT_ADDR3_B	68H-End	Reserved

The IA32_XSS MSR is zero coming out of RESET. Once IA32_XSS[bit 8] is set, system software operating at CPL= 0 can use XSAVES/XRSTORS with the appropriate requested-feature bitmap (RFBM) to manage supervisor state components in the XSAVE map. See Chapter 13, "Managing State Using the XSAVE Feature Set" of *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 1*.

36.3.6 Cycle-Accurate Mode

Intel PT can be run in a cycle-accurate mode which enables CYC packets (see Section 36.4.2.14) that provide low-level information in the processor core clock domain. This cycle counter data in CYC packets can be used to compute IPC (Instructions Per Cycle), or to track wall-clock time on a fine-grain level.

To enable cycle-accurate mode packet generation, software should set IA32_RTIT_CTL.CYCEn=1. It is recommended that software also set TSCEn=1 anytime cycle-accurate mode is in use. With this, all CYC-eligible packets will be preceded by a CYC packet, the payload of which indicates the number of core clock cycles since the last CYC packet. In cases where multiple CYC-eligible packets are generated in a single cycle, only a single CYC will be generated before the CYC-eligible packets, otherwise each CYC-eligible packet will be preceded by its own CYC. The CYC-eligible packets are:

- TNT, TIP, TIP.PGE, TIP.PGD, MODE.EXEC, MODE.TSX, PIP, VMCS, OVF, MTC, TSC

TSC packets are generated when there is insufficient information to reconstruct wall-clock time, due to tracing being disabled (TriggerEn=0), or power down scenarios like a transition to a deep-sleep MWAIT C-state. In this case, the CYC that is generated along with the TSC will indicate the number of cycles actively tracing (those powered up, with TriggerEn=1) executed between the last CYC packet and the TSC packet. And hence the amount of time spent while tracing is inactive can be inferred from the difference in time between that expected based on the CYC value, and the actual time indicated by the TSC.

Additional CYC packets may be sent stand-alone, so that the processor can ensure that the decoder is aware of the number of cycles that have passed before the internal hardware counter wraps, or is reset due to other micro-architectural condition. There is no guarantee at what intervals these standalone CYC packets will be sent, except that they will be sent before the wrap occurs. An illustration is given below.

Example 36-1. An Illustrative CYC Packet Example

Time (cycles)	Instruction Snapshot	Generated Packets	Comment
x	call %eax	CYC(?), TIP	?Elapsed cycles from the previous CYC unknown
x + 2	call %ebx	CYC(2), TIP	1 byte CYC packet; 2 cycles elapsed from the previous CYC
x + 8	jnz Foo (not taken)	CYC(6)	1 byte CYC packet
x + 9	ret (compressed)		
x + 12	jnz Bar (taken)		
x + 16	ret (uncompressed)	TNT, CYC(8), TIP	1 byte CYC packet
x + 4111		CYC(4095)	2 byte CYC packet
x + 12305		CYC(8194)	3 byte CYC packet
x + 16332	mov cr3, %ebx	CYC(4027), PIP	2 byte CYC packet

36.3.6.1 Cycle Counter

The cycle counter is implemented in hardware (independent of the time stamp counter or performance monitoring counters), and is a simple incrementing counter that does not saturate, but rather wraps. The size of the counter is implementation specific.

The cycle counter is reset to zero any time that TriggerEn is cleared, and when a CYC packet is sent. The cycle counter will continue to count when ContextEn or FilterEn are cleared, and cycle packets will still be generated. It will not count during sleep states that result in Intel PT logic being powered-down, but will count up to the point where clocks are disabled, and resume counting once they are re-enabled.

36.3.6.2 Cycle Packet Semantics

Cycle-accurate mode adheres to the following protocol:

- All packets that precede a CYC packet represent instructions or events that took place before the CYC time.
- All packets that follow a CYC packet represent instructions or events that took place at the same time as, or after, the CYC time.

- The CYC-eligible packet that immediately follows a CYC packet represents an instruction or event that took place at the same time as the CYC time.

These items above give the decoder a means to apply CYC packets to a specific instruction in the assembly stream. Most packets represent a single instruction or event, and hence the CYC packet that precedes each of those packets represents the retirement time of that instruction or event. In the case of TNT packets, up to 6 conditional branches and/or compressed RETs may be contained in the packet. In this case, the preceding CYC packet provides the retirement time of the first branch in the packet. It is possible that multiple branches retired in the same cycle as that first branch in the TNT, but the protocol will not make that obvious. Also note that a MTC packet could be generated in the same cycle as the first JCC in the TNT packet. In this case, the CYC would precede both the MTC and the TNT, and apply to both.

Note that there are times when the cycle counter will stop counting, though cycle-accurate mode is enabled. After any such scenario, a CYC packet followed by TSC packet will be sent. See Section 36.8.3.2 to understand how to interpret the payload values

Multi-packet Instructions or Events

Some operations, such as interrupts or task switches, generate multiple packets. In these cases, multiple CYC packets may be sent for the operation, preceding each CYC-eligible packet in the operation. An example, using a task switch on a software interrupt, is shown below.

Example 36-2. An Example of CYC in the Presence of Multi-Packet Operations

Time (cycles)	Instruction Snapshot	Generated Packets
x	jnz Foo (not taken)	CYC(?),
x + 2	ret (compressed)	
x + 8	jnz Bar (taken)	
x + 9	jmp %eax	TNT, CYC(9), TIP
x + 12	jnz Bar (not taken)	CYC(3)
x + 32	int3 (task gate)	TNT, FUP, CYC(10), PIP, CYC(20), MODE.Exec, TIP

36.3.6.3 Cycle Thresholds

Software can opt to reduce the frequency of cycle packets, a trade-off to save bandwidth and intrusion at the expense of precision. This is done by utilizing a cycle threshold (see Section 36.2.5.2).

IA32_RTIT_CTL.CycThresh indicates to the processor the minimum number of cycles that must pass before the next CYC packet should be sent. If this value is 0, no threshold is used, and CYC packets can be sent every cycle in which a CYC-eligible packet is generated. If this value is greater than 0, the hardware will wait until the associated number of cycles have passed since the last CYC packet before sending another. CPUID provides the threshold options for CycThresh, see Section 36.3.1.

Note that the cycle threshold does not dictate how frequently a CYC packet will be posted, it merely assigns the maximum frequency. If the cycle threshold is 16, a CYC packet can be posted no more frequently than every 16 cycles. However, once that threshold of 16 cycles has passed, it still requires a new CYC-eligible packet to be generated before a CYC will be inserted. Table 36-16 illustrates the threshold behavior.

Table 36-16. An Illustrative CYC Packet Example

Time (cycles)	Instruction Snapshot	Threshold			
		0	16	32	64
x	jmp %eax	CYC, TIP	CYC, TIP	CYC, TIP	CYC, TIP
x + 9	call %ebx	CYC, TIP	TIP	TIP	TIP
x + 15	call %ecx	CYC, TIP	TIP	TIP	TIP
x + 30	jmp %edx	CYC, TIP	CYC, TIP	TIP	TIP
x + 38	mov cr3, %eax	CYC, PIP	PIP	CYC, PIP	PIP

Table 36-16. An Illustrative CYC Packet Example

Time (cycles)	Instruction Snapshot	Threshold			
		0	16	32	64
x + 46	jmp [%eax]	CYC, TIP	CYC, TIP	TIP	TIP
x + 64	call %edx	CYC, TIP	CYC, TIP	TIP	CYC,TIP
x + 71	jmp %edx	CYC, TIP	TIP	CYC,TIP	TIP

36.3.7 Decoder Synchronization (PSB+)

The PSB packet (Section 36.4.2.17) serves as a synchronization point for a trace-packet decoder. It is a pattern in the trace log for which the decoder can quickly scan to align packet boundaries. No legal packet combination can result in such a byte sequence. As such, it serves as the starting point for packet decode. To decode a trace log properly, the decoder needs more than simply to be aligned: it needs to know some state and potentially some timing information as well. The decoder should never need to retain any information (e.g., LastIP, call stack, compound packet event) across a PSB; all compound packet events will be completed before a PSB, and any compression state will be reset.

When a PSB packet is generated, it is followed by a PSBEND packet (Section 36.4.2.18). One or more packets may be generated in between those two packets, and these inform the decoder of the current state of the processor. These packets, known collectively as PSB+, should be interpreted as "status only", since they do not imply any change of state at the time of the PSB, nor are they associated directly with any instruction or event. Thus, the normal binding and ordering rules that apply to these packets outside of PSB+ can be ignored when these packets are between a PSB and PSBEND. They inform the decoder of the state of the processor at the time of the PSB.

PSB+ can include:

- Timestamp (TSC), if IA32_RTIT_CTL.TSCEn=1
- Timestamp-MTC Align (TMA), if IA32_RTIT_CTL.TSCEn=1 && IA32_RTIT_CTL.MTCEn=1
- Paging Info Packet (PIP), if ContextEn=1 and IA32_RTIT_CTL.OS=1
  - Includes non-Root (NR) field, if the "Suppress VMX Indications in Guest Traces" VMCS execution control is cleared
- VMCS, if post-VMXON and the "Suppress VMX Indications in Guest Traces" VMCS execution control is cleared
- Core Bus Ratio (CBR)
- MODE.TSX, if ContextEn=1 and BranchEn = 1.
- MODE.Exec, if PacketEn=1.
- Flow Update Packet (FUP), if PacketEn=1.

PSB is generated only when TriggerEn=1; hence PSB+ has the same dependencies. The ordering of packets within PSB+ is not fixed. Timing packets such as CYC and MTC may be generated between PSB and PSBEND, and their meanings are the same as outside PSB+.

Note that an overflow can occur during PSB+, and this could cause the PSBEND packet to be lost. For this reason, the OVF packet should also be viewed as terminating PSB+.

36.3.8 Internal Buffer Overflow

In the rare circumstances when new packets need to be generated but the processor's dedicated internal buffers are all full, an "internal buffer overflow" occurs. On such an overflow packet generation ceases (as packets would need to enter the processor's internal buffer) until the overflow resolves. Once resolved, packet generation resumes.

When the buffer overflow is cleared, an OVF packet (Section 36.4.2.16) is generated, and the processor ensures that packets which follow the OVF are not compressed (IP compression or RET compression) against packets that were lost.

If IA32_RTIT_CTL.BranchEn = 1, the OVF packet will be followed by a FUP if the overflow resolves while PacketEn=1. If the overflow resolves while PacketEn = 0 no packet is generated, but a TIP.PGE will naturally be generated later, once PacketEn = 1. The payload of the FUP or TIP.PGE will be the Current IP of the first instruction upon which tracing resumes after the overflow is cleared. Between the OVF and following FUP or TIP.PGE, there may be packets that do not depend on PacketEn, such as timing packets. If the overflow resolves while PacketEn=0, other packets that are not dependent on PacketEn may come before the TIP.PGE.

36.3.8.1 Overflow Impact on Enables

The address comparisons to ADDRn ranges, for IP filtering and TraceStop (Section 36.2.2.3), continue during a buffer overflow, and TriggerEn, ContextEn, and FilterEn may change during a buffer overflow. Like other packets, however, any TIP.PGE or TIP.PGD packets that would have been generated will be lost. Further, IA32_RTIT_STATUS.PacketByteCnt will not increment, since it is only incremented when packets are generated.

If a TraceStop event occurs during the buffer overflow, IA32_RTIT_STATUS.Stopped will still be set, tracing will cease as a result. However, the TraceStop packet, and any TIP.PGD that result from the TraceStop, may be dropped.

36.3.8.2 Overflow Impact on Timing Packets

Any timing packets that are generated during a buffer overflow will be dropped. If only a few MTC packets are dropped, a decoder should be able to detect this by noticing that the time value in the first MTC packet after the buffer overflow incremented by more than one. If the buffer overflow lasted long enough that 256 MTC packets are lost (and thus the MTC packet 'wraps' its 8-bit CTC value), then the decoder may be unable to properly understand the trace. This is not an expected scenario. No CYC packets are generated during overflow, even if the cycle counter wraps.

Note that, if cycle-accurate mode is enabled, the OVF packet will generate a CYC packet. Because the cycle counter counts during overflows, this CYC packet can provide the duration of the overflow. However, there is a risk that the cycle counter wrapped during the overflow, which could render this CYC misleading.

36.3.9 Operational Errors

Errors are detected as a result of packet output configuration problems, which can include output alignment issues, ToPA reserved bit violations, or overlapping packet output with restricted memory. See "ToPA Errors" in Section 36.2.4.2 for details on ToPA errors, and Section 36.2.4.4 for details on restricted memory errors. Operational errors are only detected and signaled when TraceEn=1.

When an operational error is detected, tracing is disabled and the error is logged. Specifically, IA32_RTIT_STATUS.Error is set, which will cause IA32_RTIT_STATUS.TriggerEn to be 0. This will disable generation of all packets. Some causes of operational errors may lead to packet bytes being dropped.

It should be noted that the timing of error detection may not be predictable. Errors are signaled when the processor encounters the problematic configuration. This could be as soon as packet generation is enabled but could also be later when the problematic entry or field needs to be used.

Once an error is signaled, software should disable packet generation by clearing TraceEn, diagnose and fix the error condition, and clear IA32_RTIT_STATUS.Error. At this point, packet generation can be re-enabled.

36.4 TRACE PACKETS AND DATA TYPES

This section details the data packets generated by Intel Processor Trace. It is useful for developers writing the interpretation code that will decode the data packets and apply it to the traced source code.

36.4.1 Packet Relationships and Ordering

This section introduces the concept of packet "binding", which involves determining the IP in a binary disassembly at which the change indicated by a given packet applies. Some packets have the associated IP as the payload (FUP,

TIP), while for others the decoder need only search for the next instance of a particular instruction (or instructions) to bind the packet (TNT). However, in many cases, the decoder will need to consider the relationship between packets, and to use this packet context to determine how to bind the packet.

Section 36.4.2 below provides detailed descriptions of the packets, including how packets bind to IPs in the disassembly, to other packets, or to nothing at all. Many packets listed are simple to bind, because they are generated in only a few scenarios. Those that require more consideration are typically part of "compound packet events", such as interrupts, exceptions, and some instructions, where multiple packets are generated by a single operation (instruction or event). These compound packet events frequently begin with a FUP to indicate the source address (if it is not clear from the disassembly), and are concluded by a TIP or TIP.PGD packet that indicates the destination address (if one is provided). In this scenario, the FUP is said to be "coupled" with the TIP packet.

Other packets could be in between the coupled FUP and TIP packet. Timing packets, such as TSC, MTC, CYC, or CBR, could arrive at any time, and hence could intercede in a compound packet event. If an operation changes CR3 or the processor's mode of execution, a state update packet (i.e., PIP or MODE) is generated. The state changes indicated by these intermediate packets should be applied at the IP of the TIP* packet. A summary of compound packet events is provided in Table 36-17; see Section 36.4.2 for more per-packet details and Section 36.7 for more detailed packet generation examples.

Table 36-17. Compound Packet Event Summary

Event Type	Beginning	Middle	End	Comment
Unconditional, uncompressed control-flow transfer	FUP or none	Any combination of PIP, VMCS, MODE.Exec, or none	TIP or TIP.PGD	FUP only for asynchronous events. Order of middle packets may vary. PIP/VMCS/MODE only if the operation modifies the state tracked by these respective packets
TSX Update	MODE.TSX, and (FUP or none)	None	TIP, TIP.PGD, or none	FUP TIP/TIP.PGD only for TSX abort cases
Overflow	OVF	PSB, PSBEND, or none	FUP or TIP.PGE	FUP if overflow resolves while ContextEn=1, else TIP.PGE.

36.4.2 Packet Definitions

The following description of packet definitions are in tabular format. Figure 36-3 explains how to interpret them. Packet bits listed as "RSVD" are not guaranteed to be 0.

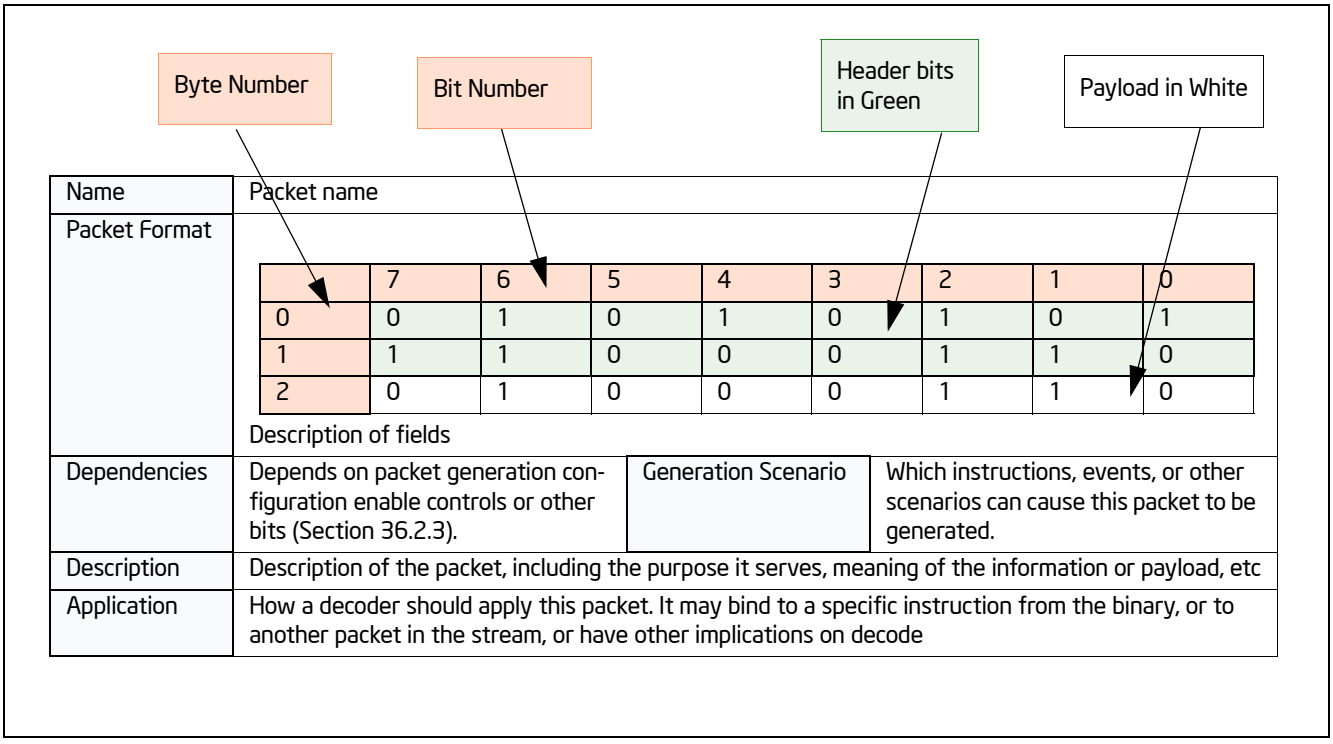

Figure 36-3. Interpreting Tabular Definition of Packet Format

36.4.2.1 Taken/Not-taken (TNT) Packet

Table 36-18. TNT Packet Definition

Name	Taken/Not-taken (TNT) Packet
Packet Format	

	7	6	5	4	3	2	1	0	
0	1	B_1	B_2	B_3	B_4	B_5	B_6	0	Short TNT

B1...BN represent the last N conditional branch or compressed RET (Section 36.4.2.2) results, such that B1 is oldest and BN is youngest. The short TNT packet can contain from 1 to 6 TNT bits. The long TNT packet can contain up from 1 to 47 TNT bits.

	7	6	5	4	3	2	1	0	
0	0	0	0	0	0	0	1	0	Long TNT
1	1	0	1	0	0	0	1	1	
2	B_{40}	B_{41}	B_{42}	B_{43}	B_{44}	B_{45}	B_{46}	B_{47}	
3	B_{32}	B_{33}	B_{34}	B_{35}	B_{36}	B_{37}	B_{38}	B_{39}	
4	B_{24}	B_{25}	B_{26}	B_{27}	B_{28}	B_{29}	B_{30}	B_{31}	
5	B_{16}	B_{17}	B_{18}	B_{19}	B_{20}	B_{21}	B_{22}	B_{23}	
6	B_8	B_9	B_{10}	B_{11}	B_{12}	B_{13}	B_{14}	B_{15}	
7	1	B_1	B_2	B_3	B_4	B_5	B_6	B_7	

Table 36-18. TNT Packet Definition

<table>
<tr><td></td><td colspan="4">Irrespective of how many TNT bits is in a packet, the last valid TNT bit is followed by a trailing 1, or Stop bit, as shown above. If the TNT packet is not full (fewer than 6 TNT bits for the Short TNT, or fewer than 47 TNT bits for the Long TNT), the Stop bit moves up, and the trailing bits of the packet are filled with 0s. Examples of these “partial TNTs” are shown below.

<table>
<tr><td></td><td>7</td><td>6</td><td>5</td><td>4</td><td>3</td><td>2</td><td>1</td><td>0</td><td></td></tr>

<tr><td>Description</td><td colspan="4">Provides the target for some control flow transfers</td></tr>
<tr><td>Application</td><td colspan="4">Anytime a TIP is encountered, it indicates that control was transferred to the IP provided in the payload.</td></tr>
<tr><td></td><td colspan="4">The source of this control flow change, and hence the IP or instruction to which it binds, depends on the packets that precede the TIP. If a TIP is encountered and all preceding packets have already been bound, then the TIP will apply to the upcoming indirect branch, far branch, or VMRESUME. However, if there was a preceding FUP that remains unbound, it will bind to the TIP. Here, the TIP provides the target of an asynchronous event or TSX abort that occurred at the IP given in the FUP payload. Note that there may be other packets, in addition to the FUP, which will bind to the TIP packet. See the packet application descriptions for other packets for details.</td></tr>
</table>

NOTES:

1. If IA32_VMX_MISC[bit 14] reports 1.
2. In a debug enclave.

IP Compression

The IP payload in a TIP. FUP, TIP.PGE, or TIP.PGD packet can vary in size, based on the mode of execution, and the use of IP compression. IP compression is an optional compression technique the processor may choose to employ to reduce bandwidth. With IP compression, the IP to be represented in the payload is compared with the last IP sent out, via any of FUP, TIP, TIP.PGE, or TIP.PGD. If that previous IP had the same upper (most significant) address bytes, those matching bytes may be suppressed in the current packet. The processor maintains an internal state of the "Last IP" that was encoded in trace packets, thus the decoder will need to keep track of the "Last IP" state in software, to match fidelity with packets generated by hardware. "Last IP" is initialized to zero, hence if the first IP in the trace may be compressed if the upper bytes are zeroes.

The "IPBytes" field of the IP packets (FUP, TIP, TIP.PGE, TIP.PGD) serves to indicate how many bytes of payload are provided, and how the decoder should fill in any suppressed bytes. The algorithm for reconstructing the IP for a TIP/FUP packet is shown in the table below.

Table 36-20. FUP/TIP IP Reconstruction

IPBytes	Uncompressed IP Value							
	63:56	55:48	47:40	39:32	31:24	23:16	15:8	7:0
000b	None, IP is out of context							
001b	Last IP[63:16]						IP Payload[15:0]	
010b	Last IP[63:32]				IP Payload[31:0]			
011b	IP Payload[47] extended		IP Payload[47:0]					
100b	Last IP [63:48]		IP Payload[47:0]					
101b	Reserved							
110b	IP Payload[63:0]							
111b	Reserved							

The processor-internal Last IP state is guaranteed to be reset to zero when a PSB is sent out. This means that the IP that follows the PSB with either be un-compressed (011b or 110b, see Table 36-20), or compressed against zero.

At times, "IPbytes" will have a value of 0. As shown above, this does not mean that the IP payload matches the full address of the last IP, but rather that the IP for this packet was suppressed. This is used for cases where the IP that applies to the packet is out of context. An example is the TIP.PGD sent on a SYSCALL, when tracing only USR code. In that case, no TargetIP will be included in the packet, since that would expose an instruction point at CPL = 0. When the IP payload is suppressed in this manner, Last IP is not cleared, and instead refers to the last IP packet with a non-zero IPBytes field.

On processors that support a maximum linear address size of 32 bits, IP payloads may never exceed 32 bits (IPBytes <= 010b).

Indirect Transfer Compression for Returns (RET)

In addition to IP compression, TIP packets for near return (RET) instructions can also be compressed. If the RET target matches the next IP of the corresponding CALL, then the TIP packet is unneeded, since the decoder can deduce the target IP by maintaining a CALL/RET stack of its own.

A CALL/RET stack can be maintained by the decoder by doing the following:

1. Allocate space to store 64 RET targets.
2. For near CALLs, push the Next IP onto the stack. Once the stack is full, new CALLs will force the oldest entry off the end of the stack, such that only the youngest 64 entries are stored. Note that this excludes zero-length CALLs, which are direct near CALLs with displacement zero (to the next IP). These CALLs typically don't have matching RETs.
3. For near RETs, pop the top (youngest) entry off the stack. This will be the target of the RET.

In cases where the RET is compressed, the target is guaranteed to match the value produced in 2) above. If the target is not compressed, a TIP packet will be generated with the RET target, which may differ from 2).

The hardware ensure that packets read by the decoder will always have seen the CALL that corresponds to any compressed RET. The processor will never compress a RET across a PSB, a buffer overflow, or scenario where PacketEn=0. This means that a RET whose corresponding CALL executed while PacketEn=0, or before the last PSB, etc., will not be compressed.

If the CALL/RET stack is manipulated or corrupted by software, and thereby causes a RET to transfer control to a target that is inconsistent with the CALL/RET stack, then the RET will not be compressed, and will produce a TIP packet. This can happen, for example, if software executes a PUSH instruction to push a target onto the stack, and a later RET uses this target.

When a RET is compressed, a Taken indication is added to the TNT buffer. Because it sends no TIP packet, it also does not update the internal Last IP value, and thus the decoder should treat it the same way. If the RET is not compressed, it will generate a TIP packet (just like when RET compression is disabled, via IA32_RTIT_CTL.DisRETC). For processors that employ deferred TIPs (Section 36.4.2.3), an uncompressed RET will not be deferred, and hence will force out any accumulated TNTs or TIPs. This serves to avoid ambiguity, and make

clear to the decoder whether the near RET was compressed, and hence a bit in the in-progress TNT should be consumed, or uncompressed, in which case there will be no in-progress TNT and thus a TIP should be consumed.

Note that in the unlikely case that a RET executes in a different execution mode than the associated CALL, the decoder will need to model the same behavior with its CALL stack. For instance, if a CALL executes in 64-bit mode, a 64-bit IP value will be pushed onto the software stack. If the corresponding RET executes in 32-bit mode, then only the lower 32 target bits will be popped off of the stack, which may mean that the RET does not go to the CALL's Next IP. This is architecturally correct behavior, and this RET could be compressed, thus the decoder should match this behavior

36.4.2.3 Deferred TIPs

The processor may opt to defer sending out the TNT when TIPs are generated. Thus, rather than sending a partial TNT followed by a TIP, both packets will be deferred while the TNT accumulates more Jcc/RET results. Any number of TIP packets may be accumulated this way, such that only once the TNT is filled, or once another packet (e.g., FUP) is generated, the TNT will be sent, followed by all the deferred TIP packets, and finally terminated by the other packet(s) that forced out the TNT and TIP packets. Generation of many other packets (see list below) will force out the TNT and any accumulated TIP packets. This is an optional optimization in hardware to reduce the bandwidth consumption, and hence the performance impact, incurred by tracing.

Table 36-21. TNT Examples with Deferred TIPs

Code Flow	Packets, Non-Deferred TIPS	Packets, Deferred TIPS
0x1000 cmp %rcx, 0 0x1004 jnz Foo // not-taken 0x1008 jmp %rdx	TNT(0b0), TIP(0x1308)	
0x1308 cmp %rcx, 1 0x130c jnz Bar // not-taken 0x1310 cmp %rcx, 2 0x1314 jnz Baz // taken 0x1500 cmp %eax, 7 0x1504 jg Exit // not-taken 0x1508 jmp %r15	TNT(0b010), TIP(0x1100)	
0x1100 cmp %rbx, 1 0x1104 jg Start // not-taken 0x1108 add %rcx, %eax 0x110c ... // **an asynchronous Interrupt arrives** INThandler: 0xcc00 pop %rdx	TNT(0b0), FUP(0x110c), TIP(0xcc00)	TNT(0b00100), TIP(0x1308), TIP(0x1100), FUP(0x110c), TIP(0xcc00)

36.4.2.4 Packet Generation Enable (TIP.PGE)

Table 36-22. TIP.PGE Packet Definition

<table>
<tr><td>Name</td><td colspan="4">Target IP - Packet Generation Enable (TIP.PGE)</td></tr>
<tr><td>Packet Format</td><td colspan="4">

<tr><td>8</td><td colspan="8">TargetIP[63:56]</td></tr>
</table>
</td></tr>
<tr><td>Dependencies</td><td>PacketEn transitions to 0</td><td>Generation Scenario</td><td colspan="2">Any branch instruction, control flow transfer, or MOV CR3 that clears PacketEn, a WRMSR that disables packet generation and clears PacketEn</td></tr>
<tr><td>Description</td><td colspan="4">Indicates that PacketEn has transitioned to 0. It will include the IP at which the tracing ends, unless ContextEn= 0 or TraceEn=0 at the conclusion of the instruction or event that cleared PacketEn.
PacketEn can be cleared due to any of the enables that comprise PacketEn transitioning from 1 to 0. Examples:
▪ TriggerEn: This is cleared on software write to clear IA32_RTIT_CTL.TraceEn, or when IA32_RTIT_STATUS.Stopped is set, or on operational error. The IP payload will be suppressed in this case, and the “IPBytes” field will have the value 0.
▪ FilterEn: This is set when software jumps out of the tracing region. This region is defined by enabling IP filtering in IA32_RTIT_CTL.ADDRn_CFG, and defining the range in IA32_RTIT_ADDRn_[AB], see. Section 36.2.2.3. The IP payload will depend on the type of the branch. For conditional branches, the payload is suppressed (IPBytes = 0), and in this case the destination can be inferred from the disassembly. For any other type of branch, the IP payload will be the target of the branch.
▪ ContextEn: This can happen on a CPL change, a CR3 write or any other means of changing ContextEn. See Section 36.2.2.3 for details. In this case, when ContextEn is cleared, there will be no IP payload. The “IPBytes” field will have value 0.
Note that, in cases where a branch that would normally produce a TIP packet (i.e., far transfer, indirect branch, interrupt, etc) or TNT update (conditional branch or compressed RT) causes PacketEn to transition from 1 to 0, the TIP or TNI bit will be replaced with TIP.PGD. The payload of the TIP.PGD will be the target of the branch, unless the result of the instruction causes TraceEn or ContextEn to be cleared (ie, SYSCALL when IA32_RTIT_CTL.OS=0, In the case where a conditional branch clears FilterEn and hence PacketEn, there will be no TNT bit for this branch, replaced instead by the TIP.PGD.</td></tr>
<tr><td>Application</td><td colspan="4">TIP.PGD can be produced by any branch instructions, as well as some non-branch instructions, that clear PacketEn. When produced by a branch, it replaces any TIP or TNT update that the branch would normally produce.
In cases where there is an unbound FUP preceding the TIP.PGD, then the TIP.PGD is part of compound operation (i.e., asynchronous event or TSX abort) which cleared PacketEn. For most such cases, the TIP.PGD is simply replacing a TIP, and should be treated the same way. The TIP.PGD may or may not have an IP payload, depending on whether the operation cleared ContextEn.
If there is not an associated FUP, the binding will depend on whether there is an IP payload. If there is an IP payload, then the TIP.PGD should be applied to either the next direct branch whose target matches the TIP.PGD payload, or the next branch that would normally generate a TIP or TNT packet. If there is no IP payload, then the TIP.PGD should apply to the next branch or MOV CR3 instruction.</td></tr>
</table>

36.4.2.6 Flow Update (FUP) Packet

Table 36-24. FUP Packet Definition

<table>
<tr><td>Name</td><td colspan="4">Flow Update (FUP) Packet</td></tr>
<tr><td>Packet Format</td><td colspan="4">
<table>
<tr><th></th><th>7</th><th>6</th><th>5</th><th>4</th><th>3</th><th>2</th><th>1</th><th>0</th></tr>
<tr><td>0</td><td colspan="3">IPBytes</td><td>1</td><td>1</td><td>1</td><td>0</td><td>1</td></tr>
<tr><td>1</td><td colspan="8">IP[7:0]</td></tr>
<tr><td>2</td><td colspan="8">IP[15:8]</td></tr>
<tr><td>3</td><td colspan="8">IP[23:16]</td></tr>
<tr><td>4</td><td colspan="8">IP[31:24]</td></tr>
<tr><td>5</td><td colspan="8">IP[39:32]</td></tr>
<tr><td>6</td><td colspan="8">IP[47:40]</td></tr>
<tr><td>7</td><td colspan="8">IP[55:48]</td></tr>
<tr><td>8</td><td colspan="8">IP[63:56]</td></tr>
</table>
</td></tr>
<tr><td>Dependencies</td><td>TriggerEn & ContextEn. (Typically depends on BranchEn and FilterEn as well, see Section 36.2.2 for details.)</td><td>Generation Scenario</td><td colspan="2">Asynchronous Events (interrupts, exceptions, INIT, SIPI, SMI, VM exit[1], #MC), XBEGIN, XEND, XABORT, XACQUIRE, XRELEASE, (EENTRY, EEXIT, ERESUME, EEE, AEX,)[2], INT 0, INT 3, INT n, a WRMSR that disables packet generation.</td></tr>
<tr><td>Description</td><td colspan="4">Provides the source address for asynchronous events, and some other instructions. Is never sent alone, always sent with an associated TIP or MODE packet, and potentially others.</td></tr>
<tr><td>Application</td><td colspan="4">FUP packets provide the IP to which they bind. However, they are never standalone, but are coupled with other packets.
In TSX cases, the FUP is immediately preceded by a MODE.TSX, which binds to the same IP. A TIP will follow only in the case of TSX aborts, see Section 36.4.2.8 for details.
Otherwise, FUPs are part of compound packet events (see Section 36.4.1). In these compound cases, the FUP provides the source IP for an instruction or event, while a following TIP (or TIP.PGD) uop will provide any destination IP. Other packets may be included in the compound event between the FUP and TIP.</td></tr>
</table>

NOTES:

1. If IA32_VMX_MISC[bit 14] reports 1.
2. If Intel Software Guard Extensions is supported.

FUP IP Payload

Flow Update Packet gives the source address of an instruction when it is needed. In general, branch instructions do not need a FUP, because the source address is clear from the disassembly. For asynchronous events, however, the source address cannot be inferred from the source, and hence a FUP will be sent. Table 36-25 illustrates cases where FUPs are sent, and which IP can be expected in those cases.

Table 36-25. FUP Cases and IP Payload

Event	Flow Update IP	Comment
External Interrupt, NMI/SMI, Traps, Machine Check (trap-like), INIT/SIPI	Address of next instruction (Next IP) that would have been executed	Functionally, this matches the LBR FROM field value and also the EIP value which is saved onto the stack.
Exceptions/Faults, Machine check (fault-like)	Address of the instruction which took the exception/fault (Current IP)	This matches the similar functionality of LBR FROM field value and also the EIP value which is saved onto the stack.
Software Interrupt	Address of the software interrupt instruction (Current IP)	This matches the similar functionality of LBR FROM field value, but does not match the EIP value which is saved onto the stack (Next Linear Instruction Pointer - NLIP).
EENTER, EEXIT, ERESUME, Enclave Exiting Event (EEE), AEX[1]	Current IP of the instruction	This matches the LBR FROM field value and also the EIP value which is saved onto the stack.
XACQUIRE	Address of the X* instruction	
XRELEASE, XBEGIN, XEND, XABORT, other transactional abort	Current IP	
#SMI	IP that is saved into SMRAM	
WRMSR that clears TraceEn	Current IP	

NOTES:

1. Information on EENTER, EEXIT, ERESUME, EEE, Asynchronous Enclave eXit (AEX) can be found in *Intel® Software Guard Extensions Programming Reference*.

On a canonical fault due to sequentially fetching an instruction in non-canonical space (as opposed to jumping to non-canonical space), the IP of the fault (and thus the payload of the FUP) will be a non-canonical address. This is consistent with what is pushed on the stack for such faulting cases.

If there are post-commit task switch faults, the IP value of the FUP will be the original IP when the task switch started. This is the same value as would be seen in the LBR_FROM field. But it is a different value as is saved on the stack or VMCS.

36.4.2.7 Paging Information (PIP) Packet

Table 36-26. PIP Packet Definition

<table>
<tr><td>Name</td><td colspan="4">Paging Information (PIP) Packet</td></tr>
<tr><td>Packet Format</td><td colspan="4">
<table>
<tr><th></th><th>7</th><th>6</th><th>5</th><th>4</th><th>3</th><th>2</th><th>1</th><th>0</th></tr>
<tr><td>0</td><td>0</td><td>0</td><td>0</td><td>0</td><td>0</td><td>0</td><td>1</td><td>0</td></tr>
<tr><td>1</td><td>0</td><td>1</td><td>0</td><td>0</td><td>0</td><td>0</td><td>1</td><td>1</td></tr>
<tr><td>2</td><td colspan="7">CR3[11:5] or 0</td><td>RSVD/NR</td></tr>
<tr><td>3</td><td colspan="8">CR3[19:12]</td></tr>
<tr><td>4</td><td colspan="8">CR3[27:20]</td></tr>
<tr><td>5</td><td colspan="8">CR3[35:28]</td></tr>
<tr><td>6</td><td colspan="8">CR3[43:36]</td></tr>
<tr><td>7</td><td colspan="8">CR3[51:44]</td></tr>
</table>
</td></tr>
<tr><td>Dependencies</td><td>TriggerEn && ContextEn && IA32_RTIT_CTL.OS</td><td>Generation Scenario</td><td colspan="2">MOV CR3, Task switch, INIT, SIPI, PSB+;
If IA32_VMX_MISC[bit 14] reports 1: VM exit, VM entry</td></tr>
<tr><td>Description</td><td colspan="4">The CR3 payload shown includes only the address portion of the CR3 value. For PAE paging, CR3[11:5] are thus included. For other page modes (32-bit and IA-32e paging), these bits are 0.
This packet holds the CR3 address value. It will be generated on operations that modify CR3:
▪ MOV CR3 operation
▪ Task Switch
▪ INIT and SIPI
▪ VM exit and VM entry, if VMCS-based controls are clear (see Section 36.5.1)
PIPs are not generated, despite changes to CR3, on SMI and RSM. This is due to the special behavior on these operations, see Section for details. Note that, for some cases of task switch where CR3 is not modified, no PIP will be produced.
The purpose of the PIP is to indicate to the decoder which application is running, so that it can apply the proper binaries to the linear addresses that are being traced.
The PIP packet contains the new CR3 value when CR3 is written.
On processors that IA32_VMX_MISC[bit 14] reports 0, bit 0 of byte 2 is reserved, and no VM exits or VM entries will be seen in the trace since these processors do not allow TraceEn to be set post-VMXON.
On processors that IA32_VMX_MISC[bit 14] reports 1, PIPs that are generated in VMX non-root operation can be configured via the VMCS execution control to set the NR bit. The NR bit is clear for PIPs generated in VMX root operation or if the VMCS execution control is configured to suppress VMX indications in Guest Traces.</td></tr>
<tr><td>Application</td><td colspan="4">The purpose of the PIP packet is to help the decoder uniquely identify what software is running at any given time. When a PIP is encountered, a decoder should do the following:
1) If there was a prior unbound FUP (that is, a FUP not preceded by a packet such as MODE.TSX that consumes it, and it hence pairs with a TIP that has not yet been seen), then this PIP is part of a compound packet event (Section 36.4.1). Find the ending TIP and apply the new CR3/NR values to the TIP payload IP.
2) Otherwise, look for the next MOV CR3, far branch, or VMRESUME/VMLAUNCH in the disassembly, and apply the new CR3 to the next (or target) IP.
For examples of the packets generated by these flows, see Section 36.7.</td></tr>
</table>

36.4.2.8 MODE Packets

MODE packets keep the decoder informed of various processor modes about which it needs to know in order to properly manage the packet output, or to properly disassemble the associated binaries. MODE packets include a header and a mode byte, as shown below.

Table 36-27. General Form of MODE Packets

	7	6	5	4	3	2	1	0
0	1	0	0	1	1	0	0	1
1	Leaf ID			Mode				

The MODE Leaf ID indicates which set of mode bits are held in the lower bits.

MODE.Exec Packet

Table 36-28. MODE.Exec Packet Definition

<table>
<tr><td>Name</td><td colspan="4">MODE.Exec Packet</td></tr>
<tr><td>Packet Format</td><td colspan="4">
<table>
<tr><td></td><td>7</td><td>6</td><td>5</td><td>4</td><td>3</td><td>2</td><td>1</td><td>0</td></tr>
<tr><td>0</td><td>1</td><td>0</td><td>0</td><td>1</td><td>1</td><td>0</td><td>0</td><td>1</td></tr>
<tr><td>1</td><td>0</td><td>0</td><td>0</td><td>0</td><td>0</td><td>0</td><td>CS.D</td><td>(CS.L & LMA)</td></tr>
</table>
</td></tr>
<tr><td>Dependencies</td><td>PacketEn</td><td>Generation Scenario</td><td colspan="2">Far branch, interrupt, exception, (VM exit, VM entry,)[1] if the mode changes. PSB+, and any scenario that can generate a TIP.PGE, such that the mode may have changed since the last MODE.Exec.</td></tr>
<tr><td>Description</td><td colspan="4">Indicates whether software is in 16, 32, or 64-bit mode, by providing the CS.D and (CS.L & IA32_EFER.LMA) values. Essential for the decoder to properly disassemble the associated binary.

<table>
<tr><td>CS.D</td><td>(CS.L & IA32_EFER.LMA)</td><td>Addressing Mode</td></tr>
<tr><td>1</td><td>1</td><td>N/A</td></tr>
<tr><td>0</td><td>1</td><td>64-bit mode</td></tr>
<tr><td>1</td><td>0</td><td>32-bit mode</td></tr>
<tr><td>0</td><td>0</td><td>16-bit mode</td></tr>
</table>

MODE.Exec is sent at the time of a mode change, if PacketEn=1 at the time, or when tracing resumes, if necessary. In the former case, the MODE.Exec packet is generated along with other packets that result from the far transfer operation that changes the mode. In cases where the mode changes while PacketEn=0, the processor will send out a MODE.Exec along with the TIP.PGE when tracing resumes. The processor may opt to suppress the MODE.Exec when tracing resumes if the mode matches that from the last MODE.Exec packet, if there was no PSB in between.</td></tr>
<tr><td>Application</td><td colspan="4">MODE.Exec always immediately precedes a TIP or TIP.PGE. The mode change applies to the IP address in the payload of the next TIP or TIP.PGE.</td></tr>
</table>

NOTES:

1. If IA32_VMX_MISC[bit 14] reports 1.

MODE.TSX Packet

Table 36-29. MODE.TSX Packet Definition

<table>
<tr><td>Name</td><td colspan="4">MODE.TSX Packet</td></tr>
<tr><td>Packet Format</td><td colspan="4">
<table>
<tr><td></td><td>7</td><td>6</td><td>5</td><td>4</td><td>3</td><td>2</td><td>1</td><td>0</td></tr>
<tr><td>0</td><td>1</td><td>0</td><td>0</td><td>1</td><td>1</td><td>0</td><td>0</td><td>1</td></tr>

</table>
</td></tr>
<tr><td>Dependencies</td><td>TriggerEn and ContextEn</td><td>Generation Scenario</td><td colspan="2">XBEGIN, XEND, XABORT, XACQUIRE, XRELEASE, if INTX changes, Asynchronous TSX Abort, PSB+</td></tr>
<tr><td>Description</td><td colspan="4">Indicates when a TSX transaction (either HLE or RTM) begins, commits, or aborts. Instructions executed transactionally will be “rolled back” if the transaction is aborted.
<table>
<tr><td>TXAbort</td><td>InTX</td><td>Implication</td></tr>
<tr><td>1</td><td>1</td><td>N/A</td></tr>
<tr><td>0</td><td>1</td><td>Transaction begins, or executing transactionally</td></tr>
<tr><td>1</td><td>0</td><td>Transaction aborted</td></tr>
<tr><td>0</td><td>0</td><td>Transaction committed, or not executing transactionally</td></tr>
</table>
</td></tr>
<tr><td>Application</td><td colspan="4">If PacketEn=1, MODE.TSX always immediately precedes a FUP. If the TXAbort bit is zero, then the mode change applies to the IP address in the payload of the FUP. If TXAbort=1, then the FUP will be followed by a TIP, and the mode change will apply to the IP address in the payload of the TIP.
MODE.TSX packets may be generated when PacketEn=0, due to FilterEn=0. In this case, only the last MODE.TSX generated before TIP.PGE need be applied.</td></tr>
</table>

36.4.2.9 TraceStop Packet

Table 36-30. TraceStop Packet Definition

Name	TraceStop Packet		
Packet Format			
Dependencies	TriggerEn && ContextEn	Generation Scenario	Taken branch with target in TraceStop IP region, MOV CR3 in TraceStop IP region, or WRMSR that sets TraceEn in TraceStop IP region.
Description	Indicates when software has entered a user-configured TraceStop region. When the IP matches a TraceStop range while ContextEn and TriggerEn are set, a TraceStop action occurs. This disables tracing by setting IA32_RTIT_STATUS.Stopped, thereby clearing TriggerEn, and causes a TraceStop packet to be generated. The TraceStop action also forces FilterEn to 0. Note that TraceStop may not force a flush of internally buffered packets, and thus trace packet generation should still be manually disabled by clearing IA32_RTIT_CTL.TraceEn before examining output.See Section 36.2.2.3 for more details.		
Application	.If TraceStop follows a TIP.PGD (before the next TIP.PGE), then it was triggered either by the instruction that cleared PacketEn, or it was triggered by some later instruction that executed while FilterEn=0. In either case, the TraceStop can be applied at the IP of the TIP.PGD (if any). If TraceStop follows a TIP.PGE (before the next TIP.PGD), it should be applied at the last known IP.		

	7	6	5	4	3	2	1	0
0	0	0	0	0	0	0	1	0
1	1	0	0	0	0	0	1	1

36.4.2.10 Core:Bus Ratio (CBR) Packet

Table 36-31. CBR Packet Definition

Name	Core:Bus Ratio (CBR) Packet		
Packet Format			
Dependencies	TriggerEn	Generation Scenario	After any frequency change, on C-state wake up, PSB+, and after enabling trace packet generation.
Description	Indicates the core:bus ratio of the processor core. Useful for correlating wall-clock time and cycle time.		
Application	All packets following the CBR represent instructions that executed with the new core:bus ratio, while all preceding packets (aside from timing packets) represent instructions that executed with the prior ratio. There is not a precise IP provided, to which to bind the CBR packet.		

	7	6	5	4	3	2	1	0
0	0	0	0	0	0	0	1	0
1	0	0	0	0	0	0	1	1
2	Core:Bus Ratio							
3	Reserved							

36.4.2.11 Timestamp Counter (TSC) Packet

Table 36-32. TSC Packet Definition

<table>
<tr><td>Name</td><td colspan="4">Timestamp Counter (TSC) Packet</td></tr>
<tr><td>Packet Format</td><td colspan="4">
<table>
<tr><td></td><td>7</td><td>6</td><td>5</td><td>4</td><td>3</td><td>2</td><td>1</td><td>0</td></tr>
<tr><td>0</td><td>0</td><td>0</td><td>0</td><td>1</td><td>1</td><td>0</td><td>0</td><td>1</td></tr>

<tr><td>5</td><td colspan="8">SW TSC[39:32]</td></tr>
<tr><td>6</td><td colspan="8">SW TSC[47:40]</td></tr>
<tr><td>7</td><td colspan="8">SW TSC[55:48]</td></tr>
</table>
</td></tr>
<tr><td>Dependencies</td><td>IA32_RTIT_CTL.TSCEn && TriggerEn</td><td>Generation Scenario</td><td colspan="2">Sent after any event that causes the processor clocks or Intel PT timing packets (such as MTC or CYC) to stop, This may include P-state changes, wake from C-state, or clock modulation. Also on transition of TraceEn from 0 to 1.</td></tr>
<tr><td>Description</td><td colspan="4">When enabled by software, a TSC packet provides the lower 7 bytes of the current TSC value, as returned by the RDTSC instruction. This may be useful for tracking wall-clock time, and synchronizing the packets in the log with other timestamped logs.</td></tr>
<tr><td>Application</td><td colspan="4">TSC packet provides a wall-clock proxy of the event which generated it (packet generation enable, sleep state wake, etc). In all cases, TSC does not precisely indicate the time of any control flow packets; however, all preceding packets represent instructions that executed before the indicated TSC time, and all subsequent packets represent instructions that executed after it. There is not a precise IP to which to bind the TSC packet.</td></tr>
</table>

36.4.2.12 Mini Time Counter (MTC) Packet

Table 36-33. MTC Packet Definition

<table>
<tr><td>Name</td><td colspan="3">Mini time Counter (MTC) Packet</td></tr>
<tr><td>Packet Format</td><td colspan="3">
<table>
<tr><td></td><td>7</td><td>6</td><td>5</td><td>4</td><td>3</td><td>2</td><td>1</td><td>0</td></tr>
<tr><td>0</td><td>0</td><td>1</td><td>0</td><td>1</td><td>1</td><td>0</td><td>0</td><td>1</td></tr>
<tr><td>1</td><td colspan="8">CTC[N+7:N]</td></tr>
</table>
</td></tr>
<tr><td>Dependencies</td><td>IA32_RTIT_CTL.MTCEn && TriggerEn</td><td>Generation Scenario</td><td>Periodic, based on the core crystal clock, or Always Running Timer (ART).</td></tr>
<tr><td>Description</td><td colspan="3">When enabled by software, an MTC packet provides a periodic indication of wall-clock time. The 8-bit CTC (Common Timestamp Copy) payload value is set to (ART >> N) & 0xFF. The frequency of the ART is related to the Maximum Non-Turbo frequency, and the ratio can be determined from CPUID leaf 15H, as described in Section 36.8.3.
Software can select the threshold N, which determines the MTC frequency by setting the IA32_RTIT_CTL.MTCFreq field (see Section 36.2.5.2) to a supported value using the lookup enumerated by CPUID (see Section 36.3.1).
See Section 36.8.3 for details on how to use the MTC payload to track TSC time.
MTC provides 8 bits from the ART, starting with the bit selected by MTCFreq to dictate the frequency of the packet. Whenever that 8-bit range being watched changes, an MTC packet will be sent out with the new value of that 8-bit range. This allows the decoder to keep track of how much wall-clock time has elapsed since the last TSC packet was sent, by keeping track of how many MTC packets were sent and what their value was. The decoder can infer the truncated bits, CTC[N-1:0], are 0 at the time of the MTC packet.
There are cases in which MTC packet can be dropped, due to overflow or other micro-architectural conditions. The decoder should be able to recover from such cases by checking the 8-bit payload of the next MTC packet, to determine how many MTC packets were dropped. It is not expected that >256 consecutive MTC packets should ever be dropped.</td></tr>
<tr><td>Application</td><td colspan="3">MTC does not precisely indicate the time of any other packet, nor does it bind to any IP. However, all preceding packets represent instructions or events that executed before the indicated ART time, and all subsequent packets represent instructions that executed after, or at the same time as, the ART time.</td></tr>
</table>

36.4.2.13 TSC/MTC Alignment (TMA) Packet

Table 36-34. TMA Packet Definition

<table>
<tr><td>Name</td><td colspan="4">TSC/MTC Alignment (TMA) Packet</td></tr>
<tr><td>Packet Format</td><td colspan="4">
<table>
<tr><th></th><th>7</th><th>6</th><th>5</th><th>4</th><th>3</th><th>2</th><th>1</th><th>0</th></tr>
<tr><td>0</td><td>0</td><td>0</td><td>0</td><td>0</td><td>0</td><td>0</td><td>1</td><td>0</td></tr>
<tr><td>1</td><td>0</td><td>1</td><td>1</td><td>1</td><td>0</td><td>0</td><td>1</td><td>1</td></tr>
<tr><td>2</td><td colspan="8">CTC[7:0]</td></tr>
<tr><td>3</td><td colspan="8">CTC[15:8]</td></tr>
<tr><td>4</td><td colspan="7">Reserved</td><td>0</td></tr>
<tr><td>5</td><td colspan="8">FastCounter[7:0]</td></tr>
<tr><td>6</td><td colspan="7">Reserved</td><td>FC[8]</td></tr>
</table>
</td></tr>
<tr><td>Dependencies</td><td>IA32_RTIT_CTL.MTCEn && IA32_RTIT_CTL.TSCEn && TriggerEn</td><td>Generation Scenario</td><td colspan="2">Sent with any TSC packet.</td></tr>
<tr><td>Description</td><td colspan="4">The TMA packet serves to provide the information needed to allow the decoder to correlate MTC packets with TSC packets. With this packet, when a MTC packet is encountered, the decoder can determine how many timestamp counter ticks have passed since the last TSC or MTC packet. See Section 36.8.3.2 for details on how to make this calculation.</td></tr>
<tr><td>Application</td><td colspan="4">TMA is always sent immediately following a TSC packet, and the payload values are consistent with the TSC payload value. Thus the application of TMA matches that of TSC.</td></tr>
</table>

36.4.2.14 Cycle Count Packet (CYC) Packet

Table 36-35. Cycle Count Packet Definition

<table>
<tr><td>Name</td><td colspan="4">Cycle Count (CYC) Packet</td></tr>
<tr><td>Packet Format</td><td colspan="4">
<table>
<tr><th></th><th>7</th><th>6</th><th>5</th><th>4</th><th>3</th><th>2</th><th>1</th><th>0</th></tr>
<tr><td>0</td><td colspan="5">Cycle Counter[4:0]</td><td>Exp</td><td>1</td><td>1</td></tr>
<tr><td>1</td><td colspan="7">Cycle Counter[11:5]</td><td>Exp</td></tr>
<tr><td>2</td><td colspan="7">Cycle Counter[18:12]</td><td>Exp</td></tr>
<tr><td>...</td><td colspan="8">... (if Exp = 1 in the previous byte)</td></tr>
</table>
</td></tr>
<tr><td>Dependencies</td><td>IA32_RTIT_CTL.CYCEn && TriggerEn</td><td>Generation Scenario</td><td colspan="2">Can be sent at any time, though a maximum of one CYC packet is sent per core clock cycle. See Section 36.3.6 for CYC-eligible packets.</td></tr>
<tr><td>Description</td><td colspan="4">The Cycle Counter field increments at the same rate as the processor core clock ticks, but with a variable length format (using a trailing EXP bit field) and a range-capped byte length.
If the CYC value is less than 32, a 1-byte CYC will be generated, with Exp=0. If the CYC value is between 32 and 4095 inclusive, a 2-byte CYC will be generated, with byte 0 Exp=1 and byte 1 Exp=0. And so on.
CYC provides the number of core clocks that have passed since the last CYC packet. CYC can be configured to be sent in every cycle in which an eligible packet is generated, or software can opt to use a threshold to limit the number of CYC packets, at the expense of some precision. These settings are configured using the IA32_RTIT_CTL.CycThresh field (see Section 36.2.5.2). For details on Cycle-Accurate Mode, IPC calculation, etc, see Section 36.3.6.
When CycThresh=0, and hence no threshold is in use, then a CYC packet will be generated in any cycle in which any CYC-eligible packet is generated. The CYC packet will precede the other packets generated in the cycle, and provides the precise cycle time of the packets that follow.
In addition to these CYC packets generated with other packets, CYC packets can be sent stand-alone. These packets serve simply to update the decoder with the number of cycles passed, and are used to ensure that a wrap of the processor's internal cycle counter doesn't cause cycle information to be lost. These stand-alone CYC packets do not indicate the cycle time of any other packet or operation, and will be followed by another CYC packet before any other CYC-eligible packet is seen.
When CycThresh>0, CYC packets are generated only after a minimum number of cycles have passed since the last CYC packet. Once this threshold has passed, the behavior above resumes, where CYC will either be sent in the next cycle that produces other CYC-eligible packets, or could be sent stand-alone.
When using CYC thresholds, only the cycle time of the operation (instruction or event) that generates the CYC packet is truly known. Other operations simply have their execution time bounded: they completed at or after the last CYC time, and before the next CYC time.</td></tr>
<tr><td>Application</td><td colspan="4">CYC provides the offset cycle time (since the last CYC packet) for the CYC-eligible packet that follows. If another CYC is encountered before the next CYC-eligible packet, the cycle values should be accumulated and applied to the next CYC-eligible packet.
If a CYC packet is generated by a TNT, note that the cycle time provided by the CYC packet applies to the first branch in the TNT packet.</td></tr>
</table>

36.4.2.15 VMCS Packet

<tr><td>Dependencies</td><td>TriggerEn && ContextEn; Also post-VMXON</td><td>Generation Scenario</td><td colspan="2">Generated on successful VMPTRLD, and optionally on SMM VM exit and VM entries that return from SMM (see Section 36.5).</td></tr>
<tr><td>Description</td><td colspan="4">The VMCS packet provides an address related to a VMCS pointer for a decoder to determine the transition of code contexts:
• On a successful VMPTRLD (i.e, a VMPTRLD that doesn't fault, fail, or VM exit), the VMCS packet contains the address of the current working VMCS pointer of the logical processor that will execute a VM guest context.
• On SMM VM exits, the VMCS packet provides the STM VMCS base address (SMM Transfer VMCS pointer), if VMCS-based controls are clear (see Section 36.5.1). See Section 36.6 on tracing inside and outside STM.
• On VM entries that return from SMM, the VMCS packet provides the current working VMCS pointer of the guest VM (see Section 36.6), if VMCS-based controls are clear (see Section 36.5.1). Root versus Non-Root operation can be distinguished from the PIP.NR bit.
If a VMCS packet is generated before a VMCS has been loaded, or after it has been cleared, the base address value will be all 1s.
VMCS packets will not be seen on processors with IA32_VMX_MISC[bit 14]=0, as these processors do not allow TraceEn to be set post-VMXON.</td></tr>
<tr><td>Application</td><td colspan="4">The purpose of the VMCS packet is to help the decoder uniquely identify changes in the executing software context in situations that CR3 may not be unique.
When a VMCS is encountered, a decoder should do the following:
▪ If there was a prior unbound FUP (that is, a FUP not preceded by a packet such as MODE.TSX that consumes it, and it hence pairs with a TIP that has not yet been seen), then this VMCS is part of a compound packet event (Section 36.4.1). Find the ending TIP and apply the new VMCS base pointer value to the TIP payload IP.
▪ Otherwise, look for the next VMPTRLD, VMRESUME, or VMLAUNCH in the disassembly, and apply the new VMCS base pointer on the next VM entry.
For examples of the packets generated by these flows, see Section 36.7.</td></tr>
</table>

36.4.2.16 Overflow (OVF) Packet

Table 36-37. OVF Packet Definition

Name	Overflow (OVF) Packet		
Packet Format			
Dependencies	TriggerEn	Generation Scenario	On resolution of internal buffer overflow
Description	OVF simply indicates to the decoder that an internal buffer overflow occurred, and packets were likely lost. If BranchEN= 1, OVF is followed by a FUP or TIP.PGE which will provide the IP at which packet generation resumes. See Section 36.3.8.		
Application	When an OVF packet is encountered, the decoder should skip to the IP given in the subsequent FUP or TIP.PGE. The cycle counter for the CYC packet will be reset at the time the OVF packet is sent. Software should reset its call stack depth on overflow, since no RET compression is allowed across an overflow. Similarly, any IP compression that follows the OVF is guaranteed to use as a reference LastIP the IP payload of an IP packet that preceded the overflow.

15	1	0	0	0	0	0	1	0

Table 36-38. PSB Packet Definition

Dependencies	TriggerEn	Generation Scenario	Periodic, based on the number of output bytes generated while tracing. PSB is sent when IA32_RTIT_STATUS.PacketByteCnt=0, and each time it crosses the software selected threshold after that. May be sent for other micro-architectural conditions as well.
Description	PSB is a unique pattern in the packet output log, and hence serves as a sync point for the decoder. It is a pattern that the decoder can search for in order to get aligned on packet boundaries. This packet is periodic, based on the number of output bytes, as indicated by IA32_RTIT_STATUS.PacketByteCnt. The period is chosen by software, via IA32_RTIT_CTL.PSBFreq (see Section 36.2.5.2). Note, however, that the PSB period is not precise, it simply reflects the average number of output bytes that should pass between PSBs. The processor will make a best effort to insert PSB as quickly after the selected threshold is reached as possible. The processor also may send extra PSB packets for some micro-architectural conditions. PSB also serves as the leading packet for a set of "status-only" packets collectively known as PSB+ (Section 36.3.7).		
Application	When a PSB is seen, the decoder should interpret all following packets as "status only", until either a PSBEND or OVF packet is encountered. "Status only" implies that the binding and ordering rules to which these packets normally adhere are ignored, and the state they carry can instead be applied to the IP payload in the FUP packet that is included.		

36.4.2.18 PSBEND Packet

Table 36-39. PSBEND Packet Definition

Name	PSBEND Packet		
Packet Format			
Dependencies	TriggerEn	Generation Scenario	Always follows PSB packet, separated by PSB+ packets
Description	PSBEND is simply a terminator for the series of "status only" (PSB+) packets that follow PSB (Section 36.3.7).		
Application	When a PSBEND packet is seen, the decoder should cease to treat packets as "status only".

36.5 TRACING POST-VMXON

On processors that IA32_VMX_MISC[bit 14] reports 1, TraceEn can be set post-VMXON. A series of mechanisms exist to allow the VMM to configure tracing based on the desired trace domain, and on the consumer of the trace output. The VMM can configure specific VM execution controls in the VMCS to control what virtualization-specific data are included within the trace packets (see Section 36.5.1 for details). MSR save and load lists can be employed by the VMM to restrict tracing to the desired context (see Section 36.5.2 for details). These configuration options

are summarized in Table 36-42. Table 36-42 covers common Intel PT usages while SMIs are handled by the default SMM treatment. Tracing with SMM Transfer Monitor is described in Section 36.6.

Table 36-42. Common Usages of Intel PT and VMX

Target Domain	Output Consumer	Virtualize Output	Configure VMCS Controls	TraceEN Configuration	Save/Restore MSR states of Trace Configuration
System-Wide (VMM + VMs)	Host	NA	Default Setting (no suppression)	WRMSR or XRSTORS by Host	NA
VMM Only	Intel PT Aware VMM	NA	Enable suppression	MSR load list to disable tracing in VM, enable tracing on VM exits	NA
VM Only	Intel PT Aware VMM	NA	Enable suppression	MSR load list to enable tracing in VM, disable tracing on VM exits	NA
Intel PT Aware Guest(s)	Per Guest	VMM adds trace output virtualization	Enable suppression	MSR load list to enable tracing in VM, disable tracing on VM exits	VMM Update guest state on XRSTORS-exiting VM exits

36.5.1 VMX-Specific Packets and VMCS Controls

In all of the usages of VMX and Intel PT, the decoder in the host or VMM context can identify the occurrences of VMX transitions with the aid of VMX-specific packets. Packets relevant to VMX fall into the follow two kinds:

- VMCS Packet: The VMX transitions of individual VM can be distinguished by a decoder using the base address field in a VMCS packet. The base address field stores the VMCS pointer address of a successful VMPTRLD. A VMCS packet is sent on a successful execution of VMPTRLD. See Section 36.4.2.15 for details.
- NonRoot (NR) bit field in PIP packet: PIP packets are generated with each VM entry/exit. The NR bit in a PIP packet is set when in VMX non-Root operation. Thus a transition of the NR bit from 0 to 1 indicates the occurrence of a VM entry, and a transition of 1 to 0 indicates the occurrence of a VM exit.

Processors with IA32_VMX_MISC[bit 14]= 1 also provides VMCS controls that a VMM can configure to prevent VMX-specific information from leaking across virtualization boundaries.

Table 36-43. VMCS Controls For Intel Processor Trace

Name	Type	Bit Position	Value	Behavior
Suppress VMX Indications in Guest Traces	Secondary Processor-Based Execution Control	19	0	PIPs generated in non-Root operation will set the PIP.NR bit. PSB+ in non-Root operation will include the VMCS packet, to ensure that the decoder knows which Guest is currently in use.
			1	PIPs generated in non-Root operation will not set the PIP.NR bit. PSB+ in non-Root operation will not include the VMCS packet.
Suppress VMX packets on Exit	VM-exit Control	24	0	PIPs are generated on VM exit, with NonRoot=0. On VM exit to SMM, VMCS packets are additionally generated.
			1	No PIP is generated on VM exit, and no VMCS packet is generated on VM exit to SMM.
Suppress VMX packets on Entry	VM-entry Control	17	0	PIPs are generated on VM entry, with NonRoot=1 if the destination of the entry is non-Root operation. On VM entry to SMM, VMCS packets are additionally generated.
			1	No PIP is generated on VM entry, and no VMCS packet is generated on VM entry to SMM.

The default setting for the VMCS controls that interacts with Intel PT is to enable all VMX-specific packet information. The scenarios that would use the default setting also do not require the VMM to use MSR load list to manage the configuration of turning-on/off of trace packet generation across VM exits.

If IA32_VMX_MISC[bit 14] reports 0, any attempt to set the VMCS control bits in Table 36-43 will result in a failure on guest entry.

36.5.2 Managing Trace Packet Generation Across VMX Transitions

In tracing scenarios that collect packets for both VMX root and non-root operations, a host executive can manage the MSRs associated with trace packet generation directly. The states of these MSRs need not be modified using MSR load list or MSR save list across VMX transitions.

For tracing scenarios that collect only packets within either VMX root or non-root operations, the VMM can use the MSR load list and/or MSR save list to toggle IA32_RTIT_CTL.TraceEn.

36.5.2.1 System-Wide Tracing

When a host or VMM configures Intel PT to collect trace packets of the entire system, it can leave the VMCS controls in its default setting to allow VMX-specific packets to provide information across VMX transitions. MSR load list is not used across VM exits or VM entries, nor is VM-exit MSR save list.

The decoder will desire to identify the occurrence of VMX transitions. The packets of interests to a decoder are shown in Table 36-44.

Table 36-44. Packets on VMX Transitions (System-Wide Tracing)

Event	Packets	Description
VM exit	FUP(GuestIP)	The FUP indicates at which point in the Guest flow the VM exit occurred. This is important, since VM exit can be an asynchronous event. The IP will match that written into the VMCS.
	PIP(HostCR3, NR=0)	The PIP packet provides the new Host CR3 value, as well as indication that the logical processor is entering VMX Root operation. This allows the decoder to identify the change of executing context from guest to host and load the appropriate set of binaries to continue decode.
	TIP(HostIP)	The TIP indicates the destination IP, the IP of the first instruction to be executed in VMX Root operation. Note, this packet could be preceded by a MODE.Exec packet (Section 36.4.2.8). This is generated only in cases where CS.D or (CS.L & EFER.LMA) change during the transition.
VM entry	PIP(GuestCR3, NR=1)	The PIP packet provides the new Guest CR3 value, as well as indication that the logical processor is entering VMX non-Root operation. This allows the decoder to identify the change of executing context from host to guest and load the appropriate set of binaries to continue decode.
	TIP(GuestIP)	The TIP indicates the destination IP, the IP of the first instruction to be executed in VMX no-Root operation. This should match the IP value read out from the VMCS. Note, this packet could be preceded by a MODE.Exec packet (Section 36.4.2.8). This is generated only in cases where CS.D or (CS.L & EFER.LMA) change during the transition.

Since the packet suppression controls are cleared, the VMCS packet will be included in all PSB+ for this usage scenario. Thus the decoder can distinguish the execution context of different VMs. Additionally, it will be generated on VMPTRLD. Thus the decoder can distinguish the execution context of different VMs.

When the host VMM configures a system to collect trace packets in this scenario, it should emulate CPUID to report CPUID.(EAX=07H, ECX=0):EBX[bit 26] with 0 to guests, indicating to guests that Intel PT is not available.

VMX TSC Manipulation

The TSC packets generated while in VMX non-Root operation will include any changes resulting from the use of a VMM's use of the TSC offsetting or TSC scaling VMCS control (see Chapter 25, "VMX Non-Root Operation"). In this system-wide usage model, the decoder may need to account for the effect of per-VM adjustments in the TSC packets generated in non-Root operation and the absence of TSC adjustments in TSC packets generated in Root operation. The VMM can supply this information to the decoder.

36.5.2.2 Host-Only Tracing

When trace packets in VMX non-root operation are not desired, the VMM can use VM-entry MSR load list with IA32_RTIT_CTL.TraceEn=0 to disable trace packet generation in guests, set IA32_RTIT_CTL.TraceEn=1 via VM-exit MSR load list.

When tracing only the Host, the decoder does not need information about the guests, the VMCS controls for suppressing VMX-specific packets can be set to reduce the packets generated. VMCS packets will still be generated on successful VMPTRLD and in PSB+ generated in the Host, but these will be unused by the decoder.

The packets of interests to a decoder when trace packets are collected for host-only tracing are shown in Table 36-45.

Table 36-45. Packets on VMX Transitions (Host-Only Tracing)

Event	Packets	Description
VM exit	TIP.PGE(HostIP)	The TIP.PGE indicates that trace packet generation is enabled and gives the IP of the first instruction to be executed in VMX Root operation. Note, this packet could be preceded by a MODE.Exec packet (Section 36.4.2.8). This is generated only in cases where CS.D or (CS.L & EFER.LMA) change during the transition.
VM entry	TIP.PGD()	The TIP indicates that trace packet generation was disabled. This ensure that all buffered packets are flushed out.

36.5.2.3 Guest-Only Tracing

A VMM can configure trace packet generation while in non-root operation for guests executing normally. This is accomplished by utilizing the MSR load lists across VM exit and VM entry to confine trace packet generation to stay within the guest environment.

For this usage, the VM-entry MSR load list is programmed to turn on trace packet generation. The VM-exit MSR load list is used to clear TraceEn=0 to disable trace packet generation in the host. Further, if it is preferred that the Guest packet stream contain no indication of non-Root execution, the VMM should set 1 to the VMCS controls described in Table 36-43.

36.5.2.4 Virtualization of Guest Output Packet Streams

Each Intel PT aware guest OS can produce one or more output packet streams to destination addresses specified as guest physical address (GPA) using context-switched IA32_RTIT_OUTPUT_BASE within the guest. The processor generates trace packets to the platform physical address specified in IA32_RTIT_OUTPUT_BASE, and those specified in the ToPA tables. Thus, a VMM that supports Intel PT aware guest OS may wish to virtualize the output configurations of IA32_RTIT_OUTPUT_BASE and ToPA for each trace configuration state of all the guests.

36.5.2.5 Emulation of Intel PT Traced State

If a VMM emulates an element of processor state by taking a VM exit on reads and/or writes to that piece of state, and the state element impacts Intel PT packet generation or values, it may be incumbent upon the VMM to insert or modify the output trace data.

If a VM exit is taken on a guest write to CR3 (including "MOV CR3" as well as task switches), the PIP packet normally generated on the CR3 write will be missing.

To avoid decoder confusion when the guest trace is decoded, the VMM should emulate the missing PIP by writing it into the guest output buffer. If the guest CR3 value is manipulated, the VMM may also need to manipulate the IA32_RTIT_CR3_MATCH value, in order to ensure the trace behavior matches the guest's expectation.

Similarly, if a VMM emulates the TSC value by taking a VM exit on RDTSC, the TSC packets generated in the trace may mismatch the TSC values returned by the VMM on RDTSC. To ensure that the trace can be properly aligned with software logs based on RDTSC, the VMM should either make corresponding modifications to the TSC packet values in the guest trace, or use mechanisms such as TSC offsetting or TSC scaling in place of exiting.

36.5.2.6 TSC Scaling

When TSC scaling is enabled for a guest using Intel PT, the VMM should ensure that the value of Maximum Non-Turbo Ratio[15:8] in MSR_PLATFORM_INFO (MSR 0CEH) and the TSC/"core crystal clock" ratio (EBX/EAX) in CPUID leaf 15H are set in a manner consistent with the resulting TSC rate that will be visible to the VM. This will allow the decoder to properly apply TSC packets, MTC packets (based on the core crystal clock or ART, whose frequency is indicated by CPUID leaf 15H), and CBR packets (which indicate the ratio of the processor frequency to the Max Non-Turbo frequency). Absent this, or separate indication of the scaling factor, the decoder will be unable to properly track time in the trace. See Section 36.8.3 for details on tracking time within an Intel PT trace.

36.5.2.7 Failed VM Entry

The packets generated by a failed VMentry depend both on the VMCS configuration, as well as on the type of failure. The results to expect are summarized in the table below. Note that packets in *italics* may or may not be generated, depending on implementation choice, and the point of failure.

Table 36-46. Packets on a Failed VM Entry

Usage Model	Entry Configuration	Early Failure (fall through to Next IP)	Late Failure (VM exit)
System-Wide	No MSR load list	TIP (NextIP)	*PIP(Guest CR3, NR=1), TraceEn 0->1 Packets (See Section 36.2.5.3),* PIP(HostCR3, NR=0), TIP(HostIP)
VMM Only	MSR load list disables TraceEn	TIP (NextIP)	*TraceEn 0->1 Packets (See Section 36.2.5.3),* TIP(HostIP)
VM Only	MSR load list Enables TraceEn	None	None

36.5.2.8 VMX Abort

VMX Abort conditions take the processor into a shutdown state. On a VM exit that leads to VMX abort, some packets (FUP, PIP) may be generated, but any expected TIP, TIP.PGE, or TIP.PGD may be dropped.

36.6 TRACING AND SMM TRANSFER MONITOR (STM)

SMM Transfer Monitor is a VMM that operates inside SMM while in VMX root operation. An STM operates in conjunction with an executive monitor. The latter operates outside SMM and in VMX root operation. Transitions from the executive monitor or its VMs to the STM are called SMM VM exits. The STM returns from SMM via a VM entry to the VM in non-root operation or the executive monitor in VMX root operation.

Intel PT supports tracing in STM similar to tracing support for post-VMXON as described above in Section 36.7. As a result, on a SMM VM exit resulting from #SMI, TraceEn is not saved and then cleared. Software can save the state of the trace configuration MSRs and clear TraceEN using the MSR load/save lists.

36.7 PACKET GENERATION SCENARIOS

Table 36-47 illustrates the packets generated in various scenarios. In the heading row, PacketEn is abbreviated as PktEn, ContextEn as CntxEn. Note that this assumes that TraceEn=1 in IA32_RTIT_CTL, while TriggerEn=1 and Error=0 in IA32_RTIT_STATUS, unless otherwise specified. Entries that do not matter in packet generation are marked "D.C."

Table 36-47. Packet Generation under Different Enable Conditions

Case	Operation	PktEn Before	PktEn After	CntxEn After	Other Dependencies	Packets Output
1a	Normal non-jump operation	0	0	D.C.		None
1b	Normal non-jump operation	1	1	1		None

Table 36-47. Packet Generation under Different Enable Conditions

36.8 SOFTWARE CONSIDERATIONS

36.8.1 Tracing SMM Code

Nothing prevents an SMM handler from configuring and enabling packet generation for its own use. As described in Section , SMI will always clear TraceEn, so the SMM handler would have to set TraceEn in order to enable tracing. There are some unique aspects and guidelines involved with tracing SMM code, which follows:

1. SMM should save away the existing values of any configuration MSRs that SMM intends to modify for tracing. This will allow the non-SMM tracing context to be restored before RSM.
2. It is recommended that SMM wait until it sets CSbase to 0 before enabling packet generation, to avoid possible LIP vs RIP confusion.
3. Packet output cannot be directed to SMRR memory, even while tracing in SMM.
4. Before performing RSM, SMM should take care to restore modified configuration MSRs to the values they had immediately after #SMI. This involves first disabling packet generation by clearing TraceEn, then restoring any other configuration MSRs that were modified.
5. RSM
   - — Software must ensure that TraceEn=0 at the time of RSM. Tracing RSM is not a supported usage model, and the packets generated by RSM are undefined.
   - — For processors on which Intel PT and LBR use are mutually exclusive (see Section 36.3.1.2), any RSM during which TraceEn is restored to 1 will suspend any LBR or BTS logging.

36.8.2 Cooperative Transition of Multiple Trace Collection Agents

A third-party trace-collection tool should take into consideration the fact that it may be deployed on a processor that supports Intel PT but may run under any operating system.

In such a deployment scenario, Intel recommends that tool agents follow similar principles of cooperative transition of single-use hardware resources, similar to how performance monitoring tools handle performance monitoring hardware:

- Respect the "in-use" ownership of an agent who already configured the trace configuration MSRs, see architectural MSRs with the prefix "IA32_RTIT_" in Chapter 35, "Model-Specific Registers (MSRs)", where "in-use" can be determined by reading the "enable bits" in the configuration MSRs.
- Relinquish ownership of the trace configuration MSRs by clearing the "enabled bits" of those configuration MSRs.

36.8.3 Tracking Time

This section describes the relationships of several clock counters whose update frequencies reside in different domains that feed into the timing packets. To track time, the decoder also needs to know the regularity or irregularity of the occurrences of various timing packets that store those clock counters.

Intel PT provides time information for three different but related domains:

- Processor timestamp counter

  This counter increments at the max non-turbo or P1 frequency, and its value is returned on a RDTSC. Its frequency is fixed. The TSC packet holds the lower 7 bytes of the timestamp counter value. The TSC packet occurs occasionally and are much less frequent than the frequency of the time stamp counter. The timestamp counter will continue to increment when the processor is in deep C-States, with the exception of processors reporting CPUID.80000007H:EDX.InvariantTSC[bit 8] =0.
- Core crystal clock

  The ratio of the core crystal clock to timestamp counter frequency is known as P, and can calculating CPUID.15H:EBX[31:0] / CPUID.15H:EAX[31:0]. The frequency of the core crystal clock is fixed and lower than that of the timestamp counter. The periodic MTC packet is generated based on software-selected multiples of the crystal clock frequency. The MTC packet is expected to occur more frequently than the TSC packet.
- Processor core clock

  The processor core clock frequency can vary due to P-state and thermal conditions. The CYC packet provides elapsed time as measured in processor core clock cycles relative to the last CYC packet.

A decoder can use all or some combination of these packets to track time at different resolutions throughout the trace packets.

36.8.3.1 Time Domain Relationships

The three domains are related by the following formula:

```
TimeStampValue = (CoreCrystalClockValue * P) + AdjustedProcessorCycles + Software_Offset;
```

The CoreCrystalClockValue can provide the coarse-grained component of the TSC value. P, or the TSC/"core crystal clock" ratio, can be derived from CPUID leaf 15H, as described in Section 36.8.3.

The AdjustedProcessorCycles component provides the fine-grained distance from the rising edge of the last core crystal clock. Specifically, it is a cycle count in the same frequency as the timestamp counter from the last crystal clock rising edge. The value is adjusted based on the ratio of the processor core clock frequency to the Maximum Non-Turbo (or P1) frequency.

The Software_Offsets component includes software offsets that are factored into the timestamp value, such as IA32_TSC_ADJUST.

36.8.3.2 Estimating TSC within Intel PT

For many usages, it may be useful to have an estimated timestamp value for all points in the trace. The formula provided in Section 36.8.3.1 above provides the framework for how such an estimate can be calculated from the various timing packets present in the trace.

The TSC packet provides the precise timestamp value at the time it is generated; however, TSC packets are infrequent, and estimates of the current timestamp value based purely on TSC packets are likely to be very inaccurate

for this reason. In order to get more precise timing information between TSC packets, CYC packets and/or MTC packets should be enabled.

MTC packets provide incremental updates of the CoreCrystalClockValue. On processors that support CPUID leaf 15H, the frequency of the timestamp counter and the core crystal clock is fixed, thus MTC packets provide a means to update the running timestamp estimate. Between two MTC packets A and B, the number of crystal clock cycles passed is calculated from the 8-bit payloads of respective MTC packets:

$(CTC_B - CTC_A)$, where $CTC_i = MTC_i[15:8] << IA32\_RTIT\_CTL.MTCFreq$ and i = A, B.

The time from a TSC packet to the subsequent MTC packet can be calculated using the TMA packet that follows the TSC packet. The TMA packet provides both the crystal clock value (lower 16 bits, in the CTC field) and the AdjustedProcessorCycles value (in the FastCounter field) that can be used in the calculation of the corresponding core crystal clock value of the TSC packet.

When the next MTC after a pair of TSC/TMA is seen, the number of crystal clocks passed since the TSC packet can be calculated by subtracting the TMA.CTC value from the time indicated by the MTC_{Next} packet by

$CTC_{Delta}[15:0] = (CTC_{Next}[15:0] - TMA.CTC[15:0])$, where $CTC_{Next} = MTC_{Payload} << IA32\_RTIT\_CTL.MTCFreq$.

The TMA.FastCounter field provides the fractional component of the TSC packet into the next crystal clock cycle.

CYC packets can provide further precision of an estimated timestamp value to many non-timing packets, by providing an indication of the time passed between other timing packets (MTCs or TSCs).

When enabled, CYC packets are sent preceding each CYC-eligible packet, and provide the number of processor core clock cycles that have passed since the last CYC packet. Thus between MTCs and TSCs, the accumulated CYC values can be used to estimate the adjusted_processor_cycles component of the timestamp value. The accumulated CPU cycles will have to be adjusted to account for the difference in frequency between the processor core clock and the P1 frequency. The necessary adjustment can be estimated using the core:bus ratio value given in the CBR packet, by multiplying the accumulated cycle count value by $P1/CBR_{payload}$.

A greater level of precision may be achieved by calculating the CPU clock frequency, see Section 36.8.3.4 below for a method to do so using Intel PT packets.

CYCs can be used to estimate time between TSCs even without MTCs, though this will likely result in a reduction in estimated TSC precision.

36.8.3.3 VMX TSC Manipulation

When software executes in non-Root operation, additional offset and scaling factors may be applied to the TSC value. These are optional, but may be enabled via VMCS controls on a per-VM basis. See Chapter 25, "VMX Non-Root Operation" for details on VMX TSC offsetting and TSC scaling.

Like the value returned by RDTSC, TSC packets will include these adjustments, but other timing packets (such as MTC, CYC, and CBR) are not impacted. In order to use the algorithm above to estimate the TSC value when TSC scaling is in use, it will be necessary for software to account for the scaling factor. See Section 36.5.2.6 for details.

36.8.3.4 Calculating Frequency with Intel PT

Because Intel PT can provide both wall-clock time and processor clock cycle time, it can be used to measure the processor core clock frequency. Either TSC or MTC packets can be used to track the wall-clock time. By using CYC packets to count the number of processor core cycles that pass in between a pair of wall-clock time packets, the ratio between processor core clock frequency and TSC frequency can be derived. If the P1 frequency is known, it can be applied to determine the CPU frequency. See Section 36.8.3.1 above for details on the relationship between TSC, MTC, and CYC.

CHAPTER 37
INTRODUCTION TO INTEL® SOFTWARE GUARD EXTENSIONS

37.1 OVERVIEW

Intel® Software Guard Extensions (Intel® SGX) is a set of instructions and mechanisms for memory accesses added to Intel® Architecture processors. Intel SGX can encompass two collections of instruction extensions, referred to as SGX1 and SGX2, see Table 37-4. The SGX1 extensions allow an application to instantiate a protected container, referred to as an enclave. An enclave is a protected area in the application's address space (see Figure 37-1), which provides confidentiality and integrity even in the presence of privileged malware. Accesses to the enclave memory area from any software not resident in the enclave are prevented. The SGX2 extensions allow additional flexibility in runtime management of enclave resources and thread execution within an enclave.

Chapter 38 covers main concepts, objects and data structure formats that interact within the Intel SGX architecture. Chapter 39 covers operational aspects ranging from preparing an enclave, transferring control to enclave code, and programming considerations for the enclave code and system software providing support for enclave execution. Chapter 40 describes the behavior of Asynchronous Enclave Exit (AEX) caused by events while executing enclave code. Chapter 41 covers the syntax and operational details of the instruction and associated leaf functions available in Intel SGX. Chapter 42 describes interaction of various aspects of IA32 and Intel® 64 architectures with Intel SGX. Chapter 43 covers Intel SGX support for application debug, profiling and performance monitoring.

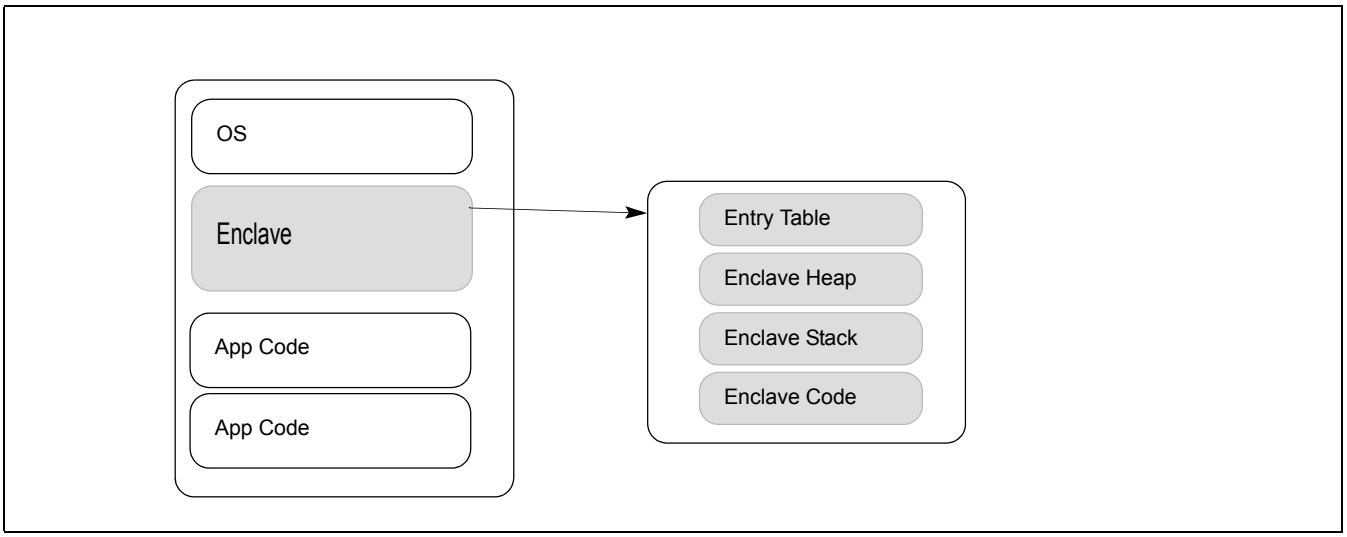

Figure 37-1. An Enclave Within the Application's Virtual Address Space

37.2 ENCLAVE INTERACTION AND PROTECTION

Intel SGX allows the protected portion of an application to be distributed in the clear. Before the enclave is built, the enclave code and data are free for inspection and analysis. The protected portion is loaded into an enclave where its code and data is measured. Once the application's protected portion of the code and data are loaded into an enclave, it is protected against external software access. An enclave can prove its identity to a remote party and provide the necessary building-blocks for secure provisioning of keys and credentials. The application can also request an enclave-specific and platform-specific key that it can use to protect keys and data that it wishes to store outside the enclave.[1]

1. For additional information, see white papers on Intel SGX at http://software.intel.com/en-us/intel-isa-extensions.

Intel SGX introduces two significant capabilities to the Intel Architecture. First is the change in enclave memory access semantics. The second is protection of the address mappings of the application.

37.3 ENCLAVE LIFE CYCLE

Enclave memory management is divided into two parts: address space allocation and memory commitment. Address space allocation is the specification of the range of logical addresses that the enclave may use. This range is called the ELRANGE. No actual resources are committed to this region. Memory commitment is the assignment of actual memory resources (as pages) within the allocated address space. This two-phase technique allows flexibility for enclaves to control their memory usage and to adjust dynamically without overusing memory resources when enclave needs are low. Commitment adds physical pages to the enclave. An operating system may support separate allocate and commit operations.

During enclave creation, code and data for an enclave are loaded from a clear-text source, i.e. from non-enclave memory.

Un-trusted application code starts using an initialized enclave typically by using the Intel SGX EENTER instruction to transfer control to the enclave code residing in the protected Enclave Page Cache (EPC). The enclave code returns to the caller via the EEXIT instruction. Upon enclave entry, control is transferred by hardware to software inside the enclave. The software inside the enclave switches the stack pointer to one inside the enclave. When returning back from the enclave, the software swaps back the stack pointer then executes the EEXIT instruction.

On processors that supports the SGX2 extensions, an enclave writer may add memory to an enclave using the SGX2 instruction set, after the enclave is built and running. These instructions allow adding additional memory resources to the enclave for use in such areas as the heap. In addition, SGX2 instructions allow the enclave to add new threads to the enclave. The SGX2 features provide additional capabilities to the software model without changing the security properties of the Intel SGX architecture.

Calling an external procedure from an enclave could be done using the EEXIT instruction. Software would use EEXIT and a software convention between the trusted section and the un-trusted section.

An active enclave consumes resource from the Enclave Page Cache (EPC, see Section 37.5). Intel SGX provides the EREMOVE instruction that an EPC manager can use to reclaim EPC pages committed to an enclave. The EPC manager uses EREMOVE on every enclave page when the enclave is torn down. After successful execution of EREMOVE the EPC page is available for allocation to another enclave.

37.4 DATA STRUCTURES AND ENCLAVE OPERATION

There are 2 main data structures associated with operating an enclave, the SGX Enclave Control Structure (SECS) and the Thread Control Structure (TCS).

There is one SECS for each enclave. The SECS contains meta-data about the enclave which is used by the hardware and cannot be directly accessed by software. Included in the SECS is a field that stores the enclave build measurement value. This field, MRENCLAVE, is initialized by the ECREATE instruction and updated by every EADD and EEXTEND. It is locked by EINIT.

Every enclave contains one or more TCS structures. The TCS contains meta-data used by the hardware to save and restore thread specific information when entering/exiting the enclave. There is one field, FLAGS, that may be accessed by software.

The SECS is created when ECREATE (see Table 37-1) is executed. The TCS can be created using the EADD instruction or the SGX2 instructions (see Table 37-2).

37.5 ENCLAVE PAGE CACHE

The Enclave Page Cache (EPC) is the secure storage used to store enclave pages when they are a part of an executing enclave.

The EPC is divided into EPC pages. An EPC page is 4KB in size and always aligned on a 4KB boundary.

Pages in the EPC can either be valid or invalid. Every valid page in the EPC belongs to one enclave instance. Each enclave instance has an EPC page that holds its SECS. The security metadata for each EPC page is held in an internal micro-architectural structure called Enclave Page Cache Map (EPCM, see Section 37.5.1).

The EPC is managed by privileged software. Intel SGX provides a set of instructions for adding and removing content to and from the EPC. The EPC may be configured by BIOS at boot time. On implementations in which EPC memory is part of system DRAM, the contents of the EPC are protected by an encryption engine.

37.5.1 Enclave Page Cache Map (EPCM)

The EPCM is a secure structure used by the processor to track the contents of the EPC. The EPCM holds one entry for each page in the EPC. The format of the EPCM is micro-architectural, and consequently is implementation dependent. However, the EPCM contains the following architectural information:

- The status of EPC page with respect to validity and accessibility.
- An SECS identifier (see Section 38.19) of the enclave to which the page belongs.
- The type of page: regular, SECS, TCS or VA.
- The linear address through which the enclave is allowed to access the page.
- The specified read/write/execute permissions on that page.

The EPCM structure is used by the CPU in the address-translation flow to enforce access-control on the EPC pages. The EPCM structure is described in Table 38-27, and the conceptual access-control flow is described in Section 38.5.

The EPCM entries are managed by the processor as part of various instruction flows.

37.6 ENCLAVE INSTRUCTIONS AND INTEL® SGX

The enclave instructions available with Intel SGX are organized as leaf functions under two instruction mnemonics: ENCLS (ring 0) and ENCLU (ring 3). Each leaf function uses EAX to specify the leaf function index, and may require additional implicit input registers as parameters. The use of EAX is implied implicitly by the ENCLS and ENCLU instructions, ModR/M byte encoding is not used with ENCLS and ENCLU. The use of additional registers does not use ModR/M encoding and is implied implicitly by the respective leaf function index.

Each leaf function index is also associated with a unique, leaf-specific mnemonic. A long-form expression of Intel SGX instruction takes the form of ENCLx[LEAF_MNEMONIC], where 'x' is either 'S' or 'U'. The long-form expression provides clear association of the privilege-level requirement of a given "leaf mnemonic". For simplicity, the unique "Leaf_Mnemonic" name is used (omitting the ENCLx for convenience) throughout in this document.

Details of Individual SGX leaf functions are described in Chapter 41. Table 37-1 provides a summary of the instruction leaves that are available in the initial implementation of Intel SGX, which is introduced in the 6th generation Intel Core processors. Table 37-1 summarizes enhancement of Intel SGX for future Intel processors.

Table 37-1. Supervisor and User Mode Enclave Instruction Leaf Functions in Long-Form of SGX1

Supervisor Instruction	Description	User Instruction	Description
ENCLS[EADD]	Add an EPC page to an enclave.	ENCLU[EENTER]	Enter an enclave.
ENCLS[EBLOCK]	Block an EPC page.	ENCLU[EEXIT]	Exit an enclave.
ENCLS[ECREATE]	Create an enclave.	ENCLU[EGETKEY]	Create a cryptographic key.
ENCLS[EDBGRD]	Read data by debugger.	ENCLU[EREPORT]	Create a cryptographic report.
ENCLS[EDBGWR]	Write data by debugger.	ENCLU[ERESUME]	Re-enter an enclave.
ENCLS[EEXTEND]	Extend EPC page measurement.		
ENCLS[EINIT]	Initialize an enclave.		
ENCLS[ELDB]	Load an EPC page in blocked state.		
ENCLS[ELDU]	Load an EPC page in unblocked state.		

Table 37-1. Supervisor and User Mode Enclave Instruction Leaf Functions in Long-Form of SGX1

Supervisor Instruction	Description	User Instruction	Description
ENCLS[EPA]	Add an EPC page to create a version array.		
ENCLS[EREMOVE]	Remove an EPC page from an enclave.		
ENCLS[ETRACK]	Activate EBLOCK checks.		
ENCLS[EWB]	Write back/invalidate an EPC page.		

Table 37-2. Supervisor and User Mode Enclave Instruction Leaf Functions in Long-Form of SGX2

Supervisor Instruction	Description	User Instruction	Description
ENCLS[EAUG]	Allocate EPC page to an existing enclave.	ENCLU[EACCEPT]	Accept EPC page into the enclave.
ENCLS[EMODPR]	Restrict page permissions.	ENCLU[EMODPE]	Enhance page permissions.
ENCLS[EMODT]	Modify EPC page type.	ENCLU[EACCEPTCOPY]	Copy contents to an augmented EPC page and accept the EPC page into the enclave.

37.7 DISCOVERING SUPPORT FOR INTEL® SGX AND ENABLING ENCLAVE INSTRUCTIONS

Detection of support of Intel SGX and enumeration of available and enabled Intel SGX resources are queried using the CPUID instruction. The enumeration interface comprises the following:

- Processor support of Intel SGX is enumerated by a feature flag in CPUID leaf 07H: CPUID.(EAX=07H, ECX=0H):EBX.SGX[bit 2]. If CPUID.(EAX=07H, ECX=0H):EBX.SGX = 1, the processor has support for Intel SGX, and requires opt-in enabling by BIOS via IA32_FEATURE_CONTROL MSR.

  If CPUID.(EAX=07H, ECX=0H):EBX.SGX = 1, CPUID will report via the available sub-leaves of CPUID.(EAX=12H) on available and/or configured Intel SGX resources.
- The available and configured Intel SGX resources enumerated by the sub-leaves of CPUID.(EAX=12H) depend on the state of BIOS configuration.

37.7.1 Intel® SGX Opt-In Configuration

On processors that support Intel SGX, IA32_FEATURE_CONTROL provides the SGX_ENABLE field (bit 18). Before system software can configure and enable Intel SGX resources, BIOS is required to set IA32_FEATURE_CONTROL.SGX_ENABLE = 1 to opt-in the use of Intel SGX by system software.

The semantics of setting SGX_ENABLE follows the rules of IA32_FEATURE_CONTROL.LOCK (bit 0). Software is considered to have opted into Intel SGX if and only if IA32_FEATURE_CONTROL.SGX_ENABLE and IA32_FEATURE_CONTROL.LOCK are set to 1. The setting of IA32_FEATURE_CONTROL.SGX_ENABLE (bit 18) is not reflected by CPUID.

Table 37-3. Intel® SGX Opt-in and Enabling Behavior

CPUID.(07H,0H):EBX.SGX	CPUID.(12H)	FEATURE_CONTROL.LOCK	FEATURE_CONTROL.SGX_ENABLE	Enclave Instruction
0	Invalid	X	X	#UD
1	Valid*	X	X	#UD**
1	Valid*	0	X	#GP
1	Valid*	1	0	#GP

Table 37-3. Intel® SGX Opt-in and Enabling Behavior

CPUID.(07H,0H):EBX.SGX	CPUID.(12H)	FEATURE_CONTROL.LOCK	FEATURE_CONTROL.SGX_ENABLE	Enclave Instruction
1	Valid*	1	1	Available (see Table 37-4 for details of SGX1 and SGX2).
* Leaf 12H enumeration results are dependent on enablement. ** See list of conditions in the #UD section of the reference pages of ENCLS and ENCLU				

37.7.2 Intel® SGX Resource Enumeration Leaves

If CPUID.(EAX=07H, ECX=0H):EBX.SGX = 1, the processor also supports querying CPUID with EAX=12H on Intel SGX resource capability and configuration. The number of available sub-leaves in leaf 12H depends on the Opt-in and system software configuration. Information returned by CPUID.12H is thread specific; software should not assume that if Intel SGX instructions are supported on one hardware thread, they are also supported elsewhere.

A properly configured processor exposes Intel SGX functionality with CPUID.EAX=12H reporting valid information (non-zero content) in three or more sub-leaves, see Table 37-4:

- CPUID.(EAX=12H, ECX=0H) enumerates Intel SGX capability, including enclave instruction opcode support.
- CPUID.(EAX=12H, ECX=1H) enumerates Intel SGX capability of processor state configuration and enclave configuration in the SECS structure (see Table 38-3).
- CPUID.(EAX=12H, ECX >1) enumerates available EPC resources.

Table 37-4. CPUID Leaf 12H, Sub-Leaf 0 Enumeration of Intel® SGX Capabilities

CPUID.(EAX=12H,ECX=0)		Description Behavior
Register	Bits	
EAX	0	SGX1: If 1, indicates leaf functions of SGX1 instruction listed in Table 37-1 are supported.
	1	SGX2: If 1, indicates leaf functions of SGX2 instruction listed in Table 37-2 are supported.
	31:2	Reserved (0)
EBX	31:0	MISCSELECT: Reports the bit vector of supported extended features that can be written to the MISC region of the SSA.
ECX	31:0	Reserved (0).
EDX	7:0	MaxEnclaveSize_Not64: the maximum supported enclave size is 2^(EDX[7:0]) bytes when not in 64-bit mode.
	15:8	MaxEnclaveSize_64: the maximum supported enclave size is 2^(EDX[15:8]) bytes when operating in 64-bit mode.
	31:16	Reserved (0).

Table 37-5. CPUID Leaf 12H, Sub-Leaf 1 Enumeration of Intel® SGX Capabilities

CPUID.(EAX=12H,ECX=1)		Description Behavior
Register	Bits	
EAX	31:0	Report the valid bits of SECS.ATTRIBUTES[31:0] that software can set with ECREATE. SECS.ATTRIBUTES[n] can be set to 1 using ECREATE only if EAX[n] is 1, where n < 32.
EBX	31:0	Report the valid bits of SECS.ATTRIBUTES[63:32] that software can set with ECREATE. SECS.ATTRIBUTES[n+32] can be set to 1 using ECREATE only if EBX[n] is 1, where n < 32.
ECX	31:0	Report the valid bits of SECS.ATTRIBUTES[95:64] that software can set with ECREATE. SECS.ATTRIBUTES[n+64] can be set to 1 using ECREATE only if ECX[n] is 1, where n < 32.

Table 37-5. CPUID Leaf 12H, Sub-Leaf 1 Enumeration of Intel® SGX Capabilities

CPUID.(EAX=12H,ECX=1)		Description Behavior
Register	Bits	
EDX	31:0	Report the valid bits of SECS.ATTRIBUTES[127:96] that software can set with ECREATE. SECS.ATTRIBUTES[n+96] can be set to 1 using ECREATE only if EDX[n] is 1, where n < 32.

On processors that support Intel SGX1 and SGX2, CPUID leaf 12H sub-leaf 2 report physical memory resources available for use with Intel SGX. These physical memory sections are typically allocated by BIOS as **Processor Reserved Memory**, and available to the OS to manage as EPC.

To enumerate how many EPC sections are available to the EPC manager, software can enumerate CPUID leaf 12H with sub-leaf index starting from 2, and decode the sub-leaf-type encoding (returned in EAX[3:0]) until the sub-leaf type is invalid. All invalid sub-leaves of CPUID leaf 12H return EAX/EBX/ECX/EDX with 0.

Table 37-6. CPUID Leaf 12H, Sub-Leaf Index 2 or Higher Enumeration of Intel® SGX Resources

CPUID.(EAX=12H,ECX > 1)		Description Behavior
Register	Bits	
EAX	3:0	0000b: This sub-leaf is invalid, EBX:EAX and EDX:ECX report 0. 0001b: This sub-leaf provides information on the Enclave Page Cache (EPC) in EBX:EAX and EDX:ECX. All other encoding are reserved.
	11:4	Reserved (0)
	31:12	If EAX[3:0] = 0001b, these are bits 31:12 of the physical address of the base of the EPC section.
EBX	19:0	If EAX[3:0] = 0001b, these are bits 51:32 of the physical address of the base of the EPC section.
	31:20	Reserved (0).
ECX	3: 0	0000b: Not valid. 0001b: The EPC section is confidentiality, integrity and replay protected. All other encoding are reserved.
	11:4	Reserved (0).
	31:12	If EAX[3:0] = 0001b, these are bits 31:12 of the size of the corresponding EPC section within the Processor Reserved Memory.
EDX	19: 0	If EAX[3:0] = 0001b, these are bits 51:32 of the size of the corresponding EPC section within the Processor Reserved Memory.
	31:20	Reserved (0)

CHAPTER 38
ENCLAVE ACCESS CONTROL AND DATA STRUCTURES

38.1 OVERVIEW OF ENCLAVE EXECUTION ENVIRONMENT

Enclave code, data and associated data structures are mapped to the ELRANGE (see Section 37.3). The linear addresses in ELRANGE, if committed, must map to a page allocated to the enclave fro the EPC (see Section 37.5). The EPC pages need not be physically contiguous. System software allocates EPC pages to various enclaves. Enclaves must abide by OS/VMM imposed segmentation and paging policies. OS/VMM-managed page tables and extended page tables provide address translation for the enclave pages. Hardware requires that these pages are properly mapped to EPC (any failure generates an exception).

Additionally, Enclave entry/exit must happen through specific enclave instructions or events:

- ENCLU[EENTER], ENCLU[ERESUME].
- ENCLU[EEXIT], Asynchronous Enclave Exit (AEX).

Attempt to execute, read or write to linear addresses mapped to EPC pages when not inside an enclave will result in undefined behavior. The processor will provide the protections as described in Section 38.4 and Section 38.5 on such accesses.

38.2 TERMINOLOGY

A memory access to the ELRANGE and initiated by an instruction executed by an enclave is called a Direct Enclave Access (Direct EA).

Memory accesses initiated by certain Intel® SGX instruction leaf functions such as ECREATE, EADD, EDBGRD, EDBGWR, ELDU/ELDB, EWB, EREMOVE, EENTER, and ERESUME to EPC pages are called Indirect Enclave Accesses (Indirect EA). Table 38-1 lists additional details of the indirect EA of SGX1 and SGX2 extensions.

Direct EAs and Indirect EAs together are called Enclave Accesses (EAs).

Any memory access that is not an Enclave Access is called a non-enclave access.

38.3 ACCESS-CONTROL REQUIREMENTS

Enclave accesses have the following access-control attributes:

- All memory accesses must conform to segmentation and paging protection mechanisms.
- Code fetches from inside an enclave to a linear address outside that enclave result in a #GP(0) exception.
- Non-enclave accesses to EPC memory result in undefined behavior. EPC memory is protected as described in Section 38.4 and Section 38.5 on such accesses.
- EPC pages must be mapped to ELRANGE at the linear address specified when the EPC page was allocated to the enclave using ENCLS[EADD] or ENCLS[EAUG] leaf functions. Enclave accesses through other linear address result in a #PF with the PFEC.SGX bit set.
- Direct EAs to any EPC pages must conform to the currently defined security attributes for that EPC page in the EPCM. These attributes may be defined at enclave creation time (EADD) or when the enclave redefines them using SGX2 instructions. The failure of these checks results in a #PF with the PFEC.SGX bit set.
  - — Target page must belong to the same enclave.
  - — Data may be written to an EPC page if the EPCM allow write access.
  - — Data may be read from an EPC page if the EPCM allow read access.
  - — Instruction fetches from an EPC page are allowed if the EPCM allows execute access.
  - — Target page must not have a restricted page type (PT_SECS, PT_TCS, PT_VA, or PT_TRIM).

— The EPC page must not be BLOCKED.
— The EPC page must not be PENDING.
— The EPC page must not be MODIFIED.

38.4 SEGMENT-BASED ACCESS CONTROL

Intel SGX architecture does not modify the segment checks performed by a logical processor. All memory accesses arising from a logical processor in protected mode (including enclave access) are subject to segmentation checks with the applicable segment register.

To ensure that outside entities do not modify the enclave's logical-to-linear address translation in an unexpected fashion, ENCLU[EENTER] and ENCLU[ERESUME] check that CS, DS, ES, and SS, if usable (i.e., not null), have segment base value of zero. A non-zero segment base value for these registers results in a #GP(0).

On enclave entry either via EENTER or ERESUME, the processor saves the contents of the external FS and GS registers, and loads these registers with values stored in the TCS at build time to enable the enclave’s use of these registers for accessing the thread-local storage inside the enclave. On EEXIT and AEX, the contents at time of entry are restored. On AEX, the values of FS and GS are saved in the SSA frame. On ERESUME, FS and GS are restored from the SSA frame. The details of these operations can be found in the descriptions of EENTER, ERESUME, EEXIT, and AEX flows.

38.5 PAGE-BASED ACCESS CONTROL

38.5.1 Access-control for Accesses that Originate from non-SGX Instructions

Intel SGX builds on the processor's paging mechanism to provide enclaves a protected execution environment. Intel SGX provides page-granular access-control for enclave pages. Enclave pages are only accessible from inside the same enclave, or through certain Intel SGX instructions.

38.5.2 Memory Accesses that Split across ELRANGE

Memory data accesses are allowed to split across ELRANGE (i.e., a part of the access is inside ELRANGE and a part of the access is outside ELRANGE) while the processor is inside an enclave. If an access splits across ELRANGE, the processor splits the access into two sub-accesses (one inside ELRANGE and the other outside ELRANGE), and each access is evaluated. A code-fetch access that splits across ELRANGE results in a #GP due to the portion that lies outside of the ELRANGE.

38.5.3 Implicit vs. Explicit Accesses

Memory accesses originating from Intel SGX instruction leaf functions are categorized as either explicit accesses or implicit accesses. Table 38-1 lists the implicit and explicit memory accesses made by Intel SGX leaf functions.

38.5.3.1 Explicit Accesses

Accesses to memory locations provided as explicit operands to Intel SGX instruction leaf functions, or their linked data structures are called explicit accesses.

Explicit accesses are always made using logical addresses. These accesses are subject to segmentation, paging, extended paging, and APIC-virtualization checks, and trigger any faults/exit associated with these checks when the access is made.

The interaction of explicit memory accesses with data breakpoints is leaf-function-specific, and is documented in Section 43.3.5.

38.5.3.2 Implicit Accesses

Accesses to data structures whose physical addresses are cached by the processor are called implicit accesses. These addresses are not passed as operands of the instruction but are implied by use of the instruction.

These accesses do not trigger any access-control faults/exits or data breakpoints. Table 38-1 lists memory objects that Intel SGX instruction leaf functions access either by explicit access or implicit access. The addresses of explicit access objects are passed via register operands with the second through fourth column of Table 38-1 matching implicitly encoded registers RBX, RCX, RDX.

Physical addresses used in different implicit accesses are cached via different instructions and for different durations. The physical address of SECS associated with each EPC page is cached at the time the page is added to the enclave via ENCLS[EADD]. This binding is severed when the corresponding page is removed from the EPC via ENCLS[EREMOVE]. Physical addresses of TCS and SSA pages are cached at the time of most-recent enclave entry. Exit from an enclave (ENCLU[EEXIT] or AEX) flushes this caching. Details of Asynchronous Enclave Exit is described in Chapter 40.

The physical addresses that are cached for use by implicit accesses are derived from logical (or linear) addresses after checks such as segmentation, paging, EPT, and APIC virtualization checks. These checks may trigger exceptions or VM exits. Note, however, that such exception or VM exits may not occur after a physical address is cached and used for an implicit access.

Table 38-1. List of Implicit and Explicit Memory Access by Intel® SGX Enclave Instructions

Instr. Leaf	Explicit 1	Explicit 2	Explicit 3	Implicit
EADD	PAGEINFO and linked structures	EPCPAGE		
EBLOCK	EPCPAGE			SECS
ECREATE	PAGEINFO and linked structures	EPCPAGE		
EDBGRD	EPCADDR	Destination		SECS
EDBGWR	EPCADDR	Source		SECS
EENTER	TCS and linked SSA			SECS
EEXIT				SECS, TCS
EEXTEND	SECS	EPCPAGE		
EGETKEY	KEYREQUEST	KEY		SECS
EINIT	SIGSTRUCT	SECS	EINITTOKEN	
ELDB/ELDU	PAGEINFO and linked structures, PCMD	EPCPAGE	VAPAGE	
EPA	EPCADDR			
EREMOVE	EPCPAGE			SECS
EREPORT	TARGETINFO	REPORTDATA	OUTPUTDATA	SECS
ERESUME	TCS and linked SSA			SECS
ETRACK	EPCPAGE

*Details of Asynchronous Enclave Exit (AEX) is described in Section 40.4				

38.6 INTEL® SGX DATA STRUCTURES OVERVIEW

Enclave operation is managed via a collection of data structures. Many of the top-level data structures contain sub-structures. The top-level data structures relate to parameters that may be used in enclave setup/maintenance, by Intel SGX instructions, or AEX event. The top-level data structures are:

- SGX Enclave Control Structure (SECS)
- Thread Control Structure (TCS)
- State Save Area (SSA)
- Page Information (PAGEINFO)
- Security Information (SECINFO)
- Paging Crypto MetaData (PCMD)
- Enclave Signature Structure (SIGSTRUCT)
- EINIT Token Structure (EINITTOKEN)
- Report Structure (REPORT)
- Report Target Info (TARGETINFO)
- Key Request (KEYREQUEST)
- Version Array (VA)
- Enclave Page Cache Map (EPCM)

Details of the top-level data structures and associated sub-structures are listed in Section 38.7 through Section 38.19.

38.7 SGX ENCLAVE CONTROL STRUCTURE (SECS)

The SECS data structure requires 4K-Bytes alignment.

Table 38-2. Layout of SGX Enclave Control Structure (SECS)

Field	OFFSET (Bytes)	Size (Bytes)	Description
SIZE	0	8	Size of enclave in bytes; must be power of 2
BASEADDR	8	8	Enclave Base Linear Address must be naturally aligned to size
SSAFRAMESIZE	16	4	Size of one SSA frame in pages (including XSAVE, pad, GPR, and conditionally MISC).
MISCSELECT	20	4	Bit vector specifying which extended features are saved to the MISC region of the SSA frame when an AEX occurs
RESERVED	24	24	
ATTRIBUTES	48	16	Attributes of the Enclave, see Table 38-3
MRENCLAVE	64	32	Measurement Register of enclave build process. See SIGSTRUCT for proper format.
RESERVED	96	32	
MRSIGNER	128	32	Measurement Register extended with the public key that verified the enclave. See SIGSTRUCT for format.
RESERVED	160	96	
ISVPRODID	256	2	Product ID of enclave
ISVSVN	258	2	Security version number (SVN) of the enclave

Table 38-2. Layout of SGX Enclave Control Structure (SECS)

Field	OFFSET (Bytes)	Size (Bytes)	Description
RESERVED	260	3836	The RESERVED field consists of the following: • EID: An 8 byte Enclave Identifier,.It's location is implementation specific, • PAD: A 352 bytes padding pattern from the Signature (used for key derivation strings). It's location is implementation specific • The remaining 3476 bytes are reserved area. The entire 3836 byte field must be cleared prior to executing ECREATE or EREPORT.

38.7.1 ATTRIBUTES

The ATTRIBUTES data structure is comprised of bit-granular fields that are used in the SECS, the REPORT and the KEYREQUEST structures. CPUID.(EAX=12H, ECX=1) enumerates a bitmap of permitted 1-setting of bits in ATTRIBUTES.

Table 38-3. Layout of ATTRIBUTES Structure

Field	Bit Position	Description
INIT	0	This bit indicates if the enclave has been initialized by EINIT. It must be cleared when loaded as part of ECREATE. For EREPORT instruction, TARGET_INFO.ATTRIBUTES[EINIT] must always be 1 to match the state after EINIT has initialized the enclave
DEBUG	1	If 1, the enclave permit debugger to read and write enclave data
MODE64BIT	2	Enclave runs in 64-bit mode
RESERVED	3	Must be Zero
PROVISIONKEY	4	Provisioning Key is available from EGETKEY
EINITTOKENKEY	5	EINIT token key is available from EGETKEY
RESERVED	63:6	
XFRM	127:64	XSAVE Feature Request Mask. See Section 42.7.

38.7.2 SECS.MISCSELECT Field

If CPUID.(EAX=12H, ECX=0):EBX[31:0] != 0, the processor can save extended information into the MISC region of SSA when an AEX occurs. An enclave writer can specify via SIGSTRUCT how to set the SECS.MISCSELECT field. The bit vector of MISCSELECT selects which extended information are to be saved in the MISC region of the SSA frame when an AEX is generated. The bit vector definition of extended information is listed in Table 38-4.

If CPUID.(EAX=12H, ECX=0):EBX[31:0] = 0, SECS.MISCSELECT field must be all zeros.

The SECS.MISCSELECT field determines the size of MISC region of the SSA frame, see Section 38.9.2.

Table 38-4. Bit Vector Layout of MISCSELECT Field of Extended Information

Field	Bit Position	Description
EXINFO	0	Report information about page fault and general protection exception that occurred inside an enclave
Reserved	31:1	Reserved (0).

38.8 THREAD CONTROL STRUCTURE (TCS)

Each executing thread in the enclave is associated with a Thread Control Structure. It requires 4K-Bytes alignment.

Table 38-5. Layout of Thread Control Structure (TCS)

Field	OFFSET (Bytes)	Size (Bytes)	Description
RESERVED	0	8	
FLAGS	8	8	The thread's execution flags (see Section 38.8.1).
OSSA	16	8	Offset of the base of the State Save Area stack, relative to the enclave base. Must be page aligned
CSSA	24	4	Current slot index of an SSA frame, cleared by EADD and EACCEPT.
NSSA	28	4	Number of available slots for SSA frames.
OENTRY	32	8	Offset in enclave to which control is transferred on EENTER relative to the base of the enclave.
AEP	40	8	The value of the Asynchronous Exit Pointer that was saved at EENTER time and is visible to EDBGRD.
OFSBASGX	48	8	Offset to add to the base address of the enclave for producing the base address of FS segment inside the enclave. Must be page aligned.
OGSBASGX	56	8	Offset to add to the base address of the enclave for producing the base address of GS segment inside the enclave. Must be page aligned.
FSLIMIT	64	4	Size to become the new FS limit in 32-bit mode
GSLIMIT	68	4	Size to become the new GS limit in 32-bit mode
RESERVED	72	4024	Must-be-zero

38.8.1 TCS.FLAGS

Table 38-6. Layout of TCS.FLAGS Field

Field	Bit Position	Description
DBGOPTIN	0	If set, allows debugging features (single-stepping, breakpoints, etc.) to be enabled and active while executing in the enclave on this TCS. Hardware clears this bit on EADD. A debugger may later modify it if the enclave's ATTRIBUTES.DEBUG is set.
RESERVED	63:1	

38.8.2 State Save Area Offset (OSSA)

The OSSA points to a stack of State Save Area (SSA) frames (see Section 38.9) used to save the processor state when an interrupt or exception occurs while executing in the enclave. Each frame in the stack consists of the XSAVE region starting at the base of a state save area frame. The GPRSGX region is top-aligned to the end of the frame. Each frame must be 4KBytes aligned and multiples of 4KBytes in size. A MISC region contains additional information written by the processor is next below the GPRSGX region inside the frame. Enclave writer can choose the pad size between the XSAVE region and the MISC region.

38.8.3 Current State Save Area Frame (CSSA)

CSSA is the index of the current SSA frame that will be used by the processor to determine where to save the processor state on an interrupt or exception that occurs while executing in the enclave. It is an index into the array of frames addressed by OSSA. CSSA is incremented on an AEX and decremented on an ERESUME.

38.8.4 Number of State Save Area Frames (NSSA)

NSSA specifies the number of SSA frames available for this TCS. There must be at least one available SSA frame when EENTER-ing the enclave or the EENTER will fail.

38.9 STATE SAVE AREA (SSA) FRAME

When an AEX occurs while running in an enclave, the architectural state is saved in the thread's current SSA frame, which is pointed to by TCS.CSSA. An SSA frame must be page aligned, and contains the following regions:

- The XSAVE region starts at the base of the SSA frame, this region contains extended feature register state in an XSAVE/FXSAVE-compatible non-compacted format.
- A Pad region: software may choose to maintain a pad region separating the XSAVE region and the MISC region. Software choose the size of the pad region according to the sizes of the MISC and GPRSGX regions.
- The GPRSGX region. The GPRSGX region is the last region of an SSA frame (see Table 38-7). This is used to hold the processor general purpose registers (RAX … R15), the RIP, the outside RSP and RBP, RFLAGS and the AEX information.
- The MISC region (If CPUIDEAX=12H, ECX=0):EBX[31:0] != 0). The MISC region is adjacent to the GRPSGX region, and may contain zero or more components of extended information that would be saved when an AEX occurs. If the MISC region is absent, the region between the GPRSGX and XSAVE regions are pads that software can use. If the MISC region is present, the region between the MISC and XSAVE regions are pads that software can use. See additional details in Table 38.9.2.

Table 38-7. Top-to-Bottom Layout of an SSA Frame

Region	Offset (Byte)	Size (Bytes)	Description
XSAVE	0	Calculate using CPUID leaf 0DH information	The size of XSAVE region in SSA is derived from the enclave's support of the collection of processor extended states that would be managed by XSAVE. The enablement of those processor extended state components in conjunction with CPUID leaf 0DH information determines the XSAVE region size in SSA.
Pad	End of XSAVE region	Chosen by enclave writer	Ensure the end of GPRSGX region is aligned to the end of a 4KB page.
MISC	base of GPRSGX -sizeof(MISC)	Calculate from highest set bit of SECS.MISCSELECT	See Section 38.9.2.
GPRSGX	SSAFRAMESIZE -1 77	176	See Table 38-8 for layout of the GPRSGX region.

38.9.1 GPRSGX Region

The layout of the GPRSGX region is shown in Table 38-8.

Table 38-8. Layout of GPRSGX Portion of the State Save Area

Field	OFFSET (Bytes)	Size (Bytes)	Description
RAX	0	8	
RCX	8	8	
RDX	16	8	
RBX	24	8	
RSP	32	8	
RBP	40	8	
RSI	48	8	

Table 38-8. Layout of GPRSGX Portion of the State Save Area

Field	OFFSET (Bytes)	Size (Bytes)	Description
RDI	56	8	
R8	64	8	
R9	72	8	
R10	80	8	
R11	88	8	
R12	96	8	
R13	104	8	
R14	112	8	
R15	120	8	
RFLAGS	128	8	Flag register.
RIP	136	8	Instruction pointer.
URSP	144	8	Non-Enclave (outside) stack pointer. Saved by EENTER, restored on AEX.
URBP	152	8	Non-Enclave (outside) RBP pointer. Saved by EENTER, restored on AEX.
EXITINFO	160	4	Contains information about exceptions that cause AEXs, which might be needed by enclave software.
RESERVED	164	4	
FSBASE	168	8	FS BASE.
GSBASE	176	8	GS BASE.

38.9.1.1 EXITINFO

EXITINFO contains the information used to report exit reasons to software inside the enclave. It is a 4 byte field laid out as in Table 38-9. The VALID bit is set only for the exceptions conditions which are reported inside an enclave. See Table 38-10 for which exceptions are reported inside the enclave. If the exception condition is not one reported inside the enclave then VECTOR and EXIT_TYPE are cleared.

Table 38-9. Layout of EXITINFO Field

Field	Bit Position	Description
VECTOR	7:0	Exception number of exceptions reported inside enclave.
EXIT_TYPE	10:8	011b: Hardware exceptions. 110b: Software exceptions. Other values: Reserved.
RESERVED	30:11	Reserved as zero.
VALID	31	0: unsupported exceptions. 1: Supported exceptions. Includes two categories: • Unconditionally supported exceptions: #DE, #DB, #BP, #BR, #UD, #MF, #AC, #XM. • Conditionally supported exception: — #PF, #GP if SECS.MISCSELECT.EXINFO = 1.

38.9.1.2 VECTOR Field Definition

Table 38-10 contains the VECTOR field. This field contains information about some exceptions which occur inside the enclave. These vector values are the same as the values that would be used when vectoring into regular exception handlers. All values not shown are not reported inside an enclave.

Table 38-10. Exception Vectors

Name	Vector #	Description
#DE	0	Divider exception.
#DB	1	Debug exception.
#BP	3	Breakpoint exception.
#BR	5	Bound range exceeded exception.
#UD	6	Invalid opcode exception.
#GP	13	General protection exception. Only reported if SECS.MISCSELECT.EXINFO = 1.
#PF	14	Page fault exception. Only reported if SECS.MISCSELECT.EXINFO = 1.
#MF	16	x87 FPU floating-point error.
#AC	17	Alignment check exceptions.
#XM	19	SIMD floating-point exceptions.

38.9.2 MISC Region

The layout of the MISC region is shown in Table 38-11. The number of components that the processor supports in the MISC region corresponds to the set bits of CPUID.(EAX=12H, ECX=0):EBX[31:0]. Each set bit in CPUID.(EAX=12H, ECX=0):EBX[31:0] has a defined size for the corresponding component, as shown in Table 38-11. Enclave writers needs to do the following:

- Decide which component available in the bitmap of CPUID.(EAX=12H, ECX=0):EBX[31:0] will be supported for the enclave.
- Allocate an SSA frame large enough to hold the components chosen above.
- Instruct each enclave builder software to set the appropriate bits in SECS.MISCSELECT.

The first component, EXINFO, starts next to the GPRSGX region. Additional components in the MISC region grow in ascending order within the MISC region towards the XSAVE region.

The size of the MISC region is calculated as follows:

- If CPUID.(EAX=12H, ECX=0):EBX[31:0] = 0, MISC region is not supported.
- If CPUID.(EAX=12H, ECX=0):EBX[31:0] != 0, the size of MISC region is derived from the highest bit set in SECS.MISCSELECT in conjunction with the offset and size information defined in Table 38-11. For example, if the highest bit set in SECS.MISCSELECT is bit 0, the MISC region size is OFFSET(EXINFO) + Sizeof(EXINFO).

Table 38-11. Layout of MISC region of the State Save Area

MISC Components	OFFSET (Bytes)	Size (Bytes)	Description
EXINFO	base(GPRSGX)-16	16	if CPUID.(EAX=12H, ECX=0):EBX[0] = 1, exception information on #GP or #PF that occurred inside an enclave can be written to the EXINFO structure if specified by SECS.MISCSELECT[0] = 1.
Future Extension	Below EXINFO	TBD	Reserved. (Zero size if CPUID.(EAX=12H, ECX=0):EBX[31:1] =0).

38.9.2.1 EXINFO Structure

Table 38-12 contains the layout of the EXINFO structure that provides additional information.

Table 38-12. Layout of EXINFO Structure

Field	OFFSET (Bytes)	Size (Bytes)	Description
MADDR	0	8	If #PF: contains the page fault linear address that caused a page fault. If #GP: the field is cleared.
ERRCD	8	4	Exception error code for either #GP or #PF.
RESERVED	12	4	

38.9.2.2 Page Fault Error Codes

Table 38-13 contains page fault error code that may be reported in EXINFO.ERRCD.

Table 38-13. Page Fault Error Codes

Name	Bit Position	Description
P	0	Same as non-SGX page fault exception P flag in Intel Architecture.
W/R	1	Same as non-SGX page fault exception W/R flag.
U/S	2	Always set to 1 (user mode reference).
RSVD	3	Same as non-SGX page fault exception RSVD flag.
I/D	4	Same as non-SGX page fault exception I/D flag.
PK	5	Protection Key induced fault.
RSVD	14:6	Reserved.
SGX	5	EPCM induced fault.
RSVD	31:5	Reserved.

38.10 PAGE INFORMATION (PAGEINFO)

PAGEINFO is an architectural data structure that is used as a parameter to the EPC-management instructions. It requires 32-Byte alignment.

Table 38-14. Layout of PAGEINFO Data Structure

Field	OFFSET (Bytes)	Size (Bytes)	Description
LINADDR	0	8	Enclave linear address.
SRCPGE	8	8	Effective address of the page where contents are located.
SECINFO/PCMD	16	8	Effective address of the SECINFO or PCMD (for ELDU, ELDB, EWB) structure for the page.
SECS	24	8	Effective address of EPC slot that currently contains the SECS.

38.11 SECURITY INFORMATION (SECINFO)

The SECINFO data structure holds meta-data about an enclave page.

Table 38-15. Layout of SECINFO Data Structure

Field	OFFSET (Bytes)	Size (Bytes)	Description
FLAGS	0	8	Flags describing the state of the enclave page; R/W by software.
RESERVED	8	56	Must be zero.

38.11.1 SECINFO.FLAGS

The SECINFO.FLAGS are a set of fields describing the properties of an enclave page.

Table 38-16. Layout of SECINFO.FLAGS Field

Field	Bit Position	Description
R	0	If 1 indicates that the page can be read from inside the enclave; otherwise the page cannot be read from inside the enclave.
W	1	If 1 indicates that the page can be written from inside the enclave; otherwise the page cannot be written from inside the enclave.
X	2	If 1 indicates that the page can be executed from inside the enclave; otherwise the page cannot be executed from inside the enclave.
PENDING	3	If 1 indicates that the page is in the PENDING state; otherwise the page is not in the PENDING state.
MODIFIED	4	If 1 indicates that the page is in the MODIFIED state; otherwise the page is not in the MODIFIED state.
PR	5	If 1 indicates that a permission restriction operation on the page is in progress, otherwise a permission restriction operation is not in progress.
RESERVED	7:6	Must be zero.
PAGE_TYPE	15:8	The type of page that the SECINFO is associated with.
RESERVED	63:16	Must be zero.

38.11.2 PAGE_TYPE Field Definition

The SECINFO flags and EPC flags contain bits indicating the type of page.

Table 38-17. Supported PAGE_TYPE

TYPE	Value	Description
PT_SECS	0	Page is an SECS.
PT_TCS	1	Page is a TCS.
PT_REG	2	Page is a normal page.
PT_VA	3	Page is a Version Array.
PT_TRIM	4	Page is in trimmed state.
	All other	Reserved.

38.12 PAGING CRYPTO METADATA (PCMD)

The PCMD structure is used to keep track of crypto meta-data associated with a paged-out page. Combined with PAGEINFO, it provides enough information for the processor to verify, decrypt, and reload a paged-out EPC page. The size of the PCMD structure (128 bytes) is architectural.

EWB calculates the MAC value and writes out the PCMD. ELDB/U reads the fields and checks the MAC.

The format of PCMD is as follows:

Table 38-18. Layout of PCMD Data Structure

Field	OFFSET (Bytes)	Size (Bytes)	Description
SECINFO	0	64	Flags describing the state of the enclave page; R/W by software.
ENCLAVEID	64	8	Enclave Identifier used to establish a cryptographic binding between paged-out page and the enclave.

Table 38-18. Layout of PCMD Data Structure

Field	OFFSET (Bytes)	Size (Bytes)	Description
RESERVED	72	40	Must be zero.
MAC	112	16	MAC for the page, page meta-data and reserved field.

38.13 ENCLAVE SIGNATURE STRUCTURE (SIGSTRUCT)

SIGSTRUCT is a structure created and signed by the enclave developer that contains information about the enclave. SIGSTRUCT is processed by the EINIT leaf function to verify that the enclave was properly built.

SIGSTRUCT includes ENCLAVEHASH as SHA256 digests as defined in FIPS PUB 180-4. The digests are byte strings of length 32 with the most significant byte of each of the 8 HASH dwords at the left most byte position.

SIGSTRUCT includes four 3072-bit integers (MODULUS, SIGNATURE, Q1, Q2). Each such integer is represented as a byte strings of length 384, with the most significant byte at the position "offset + 383", and the least significant byte at position "offset".

The (3072-bit integer) SIGNATURE should be an RSA signature, where: a) the RSA modulus (MODULUS) is a 3072-bit integer; b) the public exponent is set to 3; c) the signing procedure uses the EMSA-PKCS1-v1.5 format with DER encoding of the "DigestInfo" value as specified in of PKCS#1 v2.1/RFC 3447.

The 3072-bit integers Q1 and Q2 are defined by:

q1 = floor(Signature^2 / Modulus);

q2 = floor((Signature^3 - q1 * Signature * Modulus) / Modulus);

SIGSTRUCT must be page aligned

In column 5 of Table 38-19, 'Y' indicates that this field should be included in the signature generated by the developer.

Table 38-19. Layout of Enclave Signature Structure (SIGSTRUCT)

Field	OFFSET (Bytes)	Size (Bytes)	Description	Signed
HEADER	0	16	Must be byte stream 06000000E10000000000010000000000H	Y
VENDOR	16	4	Intel Enclave: 00008086H Non-Intel Enclave: 00000000H	Y
DATE	20	4	Build date is yyyymmdd in hex: yyyy=4 digit year, mm=1-12, dd=1-31	Y
HEADER2	24	16	Must be byte stream 01010000600000006000000001000000H	Y
SWDEFINED	40	4	Available for software use	Y
RESERVED	44	84	Must be zero	Y
MODULUS	128	384	Module Public Key (keylength=3072 bits)	N
EXPONENT	512	4	RSA Exponent = 3	N
SIGNATURE	516	384	Signature over Header and Body	N
MISCSELECT*	900	4	Bit vector specifying Extended SSA frame feature set to be used	Y
MISCMASK*	904	4	Bit vector mask of MISCSELECT to enforce	Y
RESERVED	908	20	Must be zero	Y
ATTRIBUTES	928	16	Enclave Attributes that must be set	Y
ATTRIBUTEMASK	944	16	Mask of Attributes to enforce	Y
ENCLAVEHASH	960	32	MRENCLAVE of enclave this structure applies to	Y

Table 38-19. Layout of Enclave Signature Structure (SIGSTRUCT)

Field	OFFSET (Bytes)	Size (Bytes)	Description	Signed
RESERVED	992	32	Must be zero	Y
ISVPRODID	1024	2	ISV assigned Product ID	Y
ISVSVN	1026	2	ISV assigned SVN (security version number)	Y
RESERVED	1028	12	Must be zero	N
Q1	1040	384	Q1 value for RSA Signature Verification	N
Q2	1424	384	Q2 value for RSA Signature Verification	N
* If CPUID.(EAX=12H, ECX=0):EBX[31:0] = 0, MISCSELECT must be 0. If CPUID.(EAX=12H, ECX=0):EBX[31:0] !=0, enclave writers must specify MISCSELECT such that each cleared bit in MISCMASK must also specify the corresponding bit as 0 in MISCSELECT.				

38.14 EINIT TOKEN STRUCTURE (EINITTOKEN)

The EINIT token is used by EINIT to verify that the enclave is permitted to launch. EINIT token is generated by an enclave in possession of the EINITTOKEN key (the Launch Enclave).

EINIT token must be 512-Byte aligned.

Table 38-20. Layout of EINIT Token (EINITTOKEN)

Field	OFFSET (Bytes)	Size (Bytes)	MACed	Description
DEBUG	0	4	Y	Bits 0: 1: Valid; 0: Debug. All other bits reserved.
RESERVED	4	44	Y	Must be zero.
ATTRIBUTES	48	16	Y	ATTRIBUTES of the Enclave.
MRENCLAVE	64	32	Y	MRENCLAVE of the Enclave.
RESERVED	96	32	Y	Reserved.
MRSIGNER	128	32	Y	MRSIGNER of the Enclave.
RESERVED	160	32	Y	Reserved.
CPUSVNLE	192	16	N	Launch Enclave's CPUSVN.
ISVPRODIDLE	208	02	N	Launch Enclave's ISVPRODID.
ISVSVNLE	210	02	N	Launch Enclave's ISVSVN.
RESERVED	212	24	N	Reserved.
MASKEDMISCSELECTLE	236	4		Launch Enclave's MASKEDMISCSELECT: set by the LE to the resolved MISCSELECT value, used by EGETKEY (after applying KEYREQUEST's masking).
MASKEDATTRIBUTESLE	240	16	N	Launch Enclave's MASKEDATTRIBUTES: This should be set to the LE's ATTRIBUTES masked with ATTRIBUTEMASK of the LE's KEYREQUEST.
KEYID	256	32	N	Value for key wear-out protection.
MAC	288	16	N	A cryptographic MAC on EINITTOKEN using Launch key.

38.15 REPORT (REPORT)

The REPORT structure is the output of the EREPORT instruction, and must be 512-Byte aligned.

Table 38-21. Layout of REPORT

Field	OFFSET (Bytes)	Size (Bytes)	Description
CPUSVN	0	16	The security version number of the processor.
MISCSELECT	16	4	Bit vector specifying which extended features are saved to the MISC region of the SSA frame when an AEX occurs.
RESERVED	20	28	Must be zero.
ATTRIBUTES	48	16	ATTRIBUTES of the Enclave. See Section 38.7.1.
MRENCLAVE	64	32	The value of SECS.MRENCLAVE.
RESERVED	96	32	Reserved.
MRSIGNER	128	32	The value of SECS.MRSIGNER.
RESERVED	160	96	Zero.
ISVPRODID	256	02	Product ID of enclave.
ISVSVN	258	02	Security version number (SVN) of the enclave.
RESERVED	260	60	Zero.
REPORTDATA	320	64	Data provided by the user and protected by the REPORT's MAC, and elaborate in Section 38.15.1.
KEYID	384	32	Value for key wear-out protection.
MAC	416	16	The CMAC on the report using report key.

38.15.1 REPORTDATA

REPORTDATA is a 64-Byte data structure that is provided by the enclave and included in the REPORT. It can be used to securely pass information from the enclave to the target enclave. REPORTDATA must be 128-Byte aligned.

38.16 REPORT TARGET INFO (TARGETINFO)

This structure is an input parameter to the EREPORT leaf function. The address of TARGETINFO is specified as an effective address in RBX. It is used to identify the target enclave which will be able to cryptographically verify the REPORT structure returned by EREPORT. TARGETINFO must be 512-Byte aligned.

Table 38-22. Layout of TARGETINFO Data Structure

Field	OFFSET (Bytes)	Size (Bytes)	Description
MEASUREMENT	0	32	The MRENCLAVE of the target enclave.
ATTRIBUTES	32	16	The ATTRIBUTES field of the target enclave.
RESERVED	48	4	
MISCSELECT	52	4	The MISCSELECT of the target enclave.
RESERVED	56	456	

38.17 KEY REQUEST (KEYREQUEST)

This structure is an input parameter to the EGETKEY leaf function. It is passed in as an effective address in RBX and must be 512-Byte alignment. It is used for selecting the appropriate key and any additional parameters required in the derivation of that key.

Table 38-23. Layout of KEYREQUEST Data Structure

Field	OFFSET (Bytes)	Size (Bytes)	Description
KEYNAME	0	02	Identifies the Key Required.
KEYPOLICY	02	02	Identifies which inputs are required to be used in the key derivation.
ISVSVN	04	02	The ISV security version number that will be used in the key derivation.
RESERVED	06	02	Must be zero.
CPUSVN	08	16	The security version number of the processor used in the key derivation.
ATTRIBUTEMASK	24	16	A mask defining which ATTRIBUTES bits will be included in key derivation.
KEYID	40	32	Value for key wear-out protection.
MISCMASK	72	4	A mask defining which MISCSELECT bits will be included in key derivation.
RESERVED	76	436	

38.17.1 KEY REQUEST KeyNames

Table 38-24. Supported KEYName Values

Key Name	Value	Description
EINIT_TOKEN_KEY	0	EINIT_TOKEN key
PROVISION_KEY	1	Provisioning Key
PROVISION_SEAL_KEY	2	Provisioning Seal Key
REPORT_KEY	3	Report Key
SEAL_KEY	4	Report Key
	All other	Reserved

38.17.2 Key Request Policy Structure

Table 38-25. Layout of KEYPOLICY Field

Field	Bit Position	Description
MRENCLAVE	0	If 1, derive key using the enclave's MRENCLAVE measurement register.
MRSIGNER	1	If 1, derive key using the enclave's MRSIGNER measurement register.
RESERVED	15:2	Must be zero.

38.18 VERSION ARRAY (VA)

In order to securely store the versions of evicted EPC pages, Intel SGX defines a special EPC page type called a Version Array (VA). Each VA page contains 512 slots, each of which can contain an 8-byte version number for a page evicted from the EPC. When an EPC page is evicted, software chooses an empty slot in a VA page; this slot receives the unique version number of the page being evicted. When the EPC page is reloaded, there must be a VA slot that must hold the version of the page. If the page is successfully reloaded, the version in the VA slot is cleared.

VA pages can be evicted, just like any other EPC page. When evicting a VA page, a version slot in some other VA page must be used to hold the version for the VA being evicted. A Version Array Page must be 4K-Bytes aligned.

Table 38-26. Layout of Version Array Data Structure

Field	OFFSET (Bytes)	Size (Bytes)	Description
Slot 0	0	08	Version Slot 0
Slot 1	8	08	Version Slot 1
…			
Slot 511	4088	08	Version Slot 511

38.19 ENCLAVE PAGE CACHE MAP (EPCM)

EPCM is a secure structure used by the processor to track the contents of the EPC. The EPCM holds exactly one entry for each page that is currently loaded into the EPC. EPCM is not accessible by software, and the layout of EPCM fields is implementation specific.

Table 38-27. Content of an Enclave Page Cache Map Entry

Field	Description
VALID	Indicates whether the EPCM entry is valid.
R	Read access; indicates whether enclave accesses for reads are allowed from the EPC page referenced by this entry.
W	Write access; indicates whether enclave accesses for writes are allowed to the EPC page referenced by this entry.
X	Execute access; indicates whether enclave accesses for instruction fetches are allowed from the EPC page referenced by this entry.
PT	EPCM page type (PT_SECS, PT_TCS, PT_REG, PT_VA, PT_TRIM).
ENCLAVESECS	SECS identifier of the enclave to which the EPC page belongs.
ENCLAVEADDRESS	Linear enclave address of the EPC page.
BLOCKED	Indicates whether the EPC page is in the blocked state.
PENDING	Indicates whether the EPC page is in the pending state.
MODIFIED	Indicates whether the EPC page is in the modified state.

CHAPTER 39
ENCLAVE OPERATION

The following aspects of enclave operation are described in this chapter:

- Enclave creation: Includes loading code and data from outside of enclave into the EPC and establishing the enclave entity.
- Adding pages and measuring the enclave.
- Initialization of an enclave: Finalizes the cryptographic log and establishes the enclave identity and sealing identity.
- Enclave entry and exiting including:
  - — Synchronous entry and exit.
  - — Asynchronous Enclave Exit (AEX) and resuming execution after an AEX.

39.1 CONSTRUCTING AN ENCLAVE

Figure 39-1 illustrates a typical Enclave memory layout.

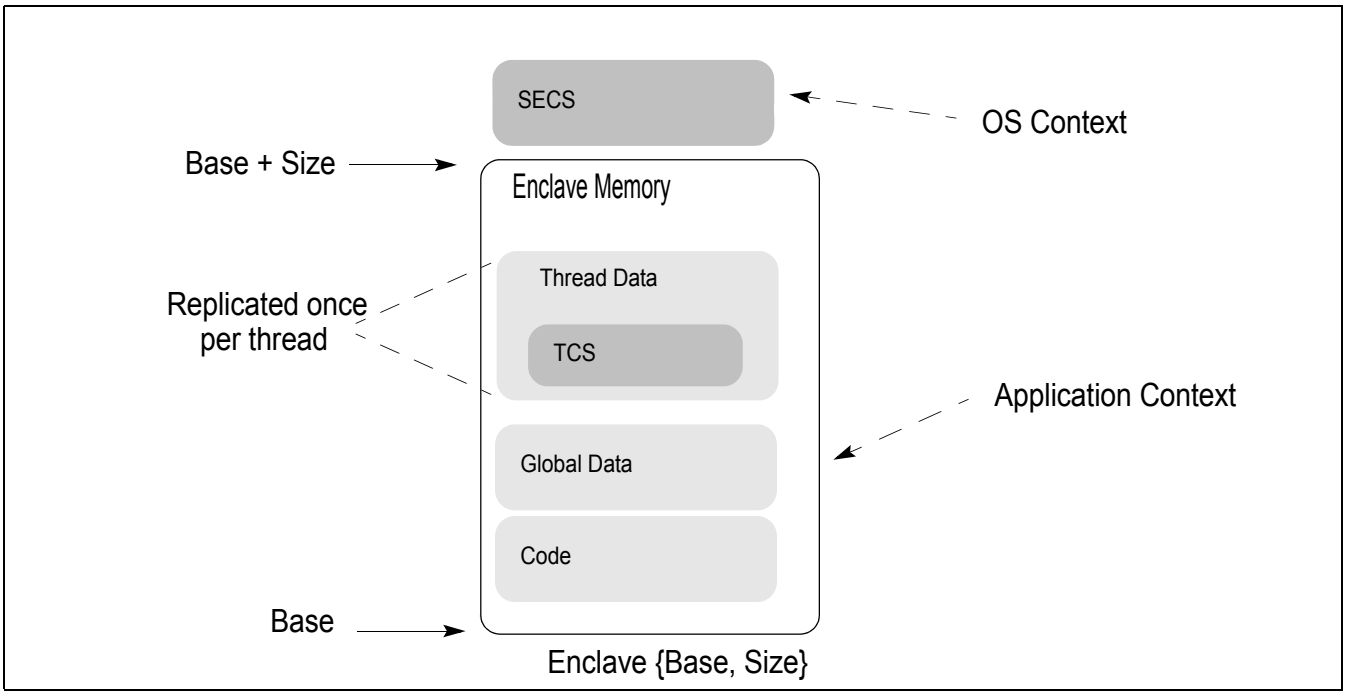

Figure 39-1. Enclave Memory Layout

The enclave creation, commitment of memory resources, and finalizing the enclave's identity with measurement comprises multiple phases. This process can be illustrated by the following exemplary steps:

1. The application hands over the enclave content along with additional information required by the enclave creation API to the enclave creation service running at ring-0.
2. The enclave creation service running at ring-0 uses the ECREATE leaf function to set up the initial environment, specifying base address and size of the enclave. This address range, the ELRANGE, is part of the application's address space. This reserves the memory range. The enclave will now reside in this address region. ECREATE

also allocates an Enclave Page Cache (EPC) page for the SGX Enclave Control Structure (SECS). Note that this page is not required to be a part of the enclave linear address space and is not required to be mapped into the process.

3. The enclave creation service uses the EADD leaf function to commit EPC pages to the enclave, and use EEXTEND to measure the committed memory content of the enclave. For each additional page to be added to the enclave:
   — Use EADD to add the new page to the enclave.
   — If the enclave developer requires measurement of the page as a proof for the content, use EEXTEND to add a measurement for 256 bytes of the page. Repeat this operation until the entire page is measured.
4. The enclave creation service uses the EINIT leaf function to complete the enclave creation process and finalize the enclave measurement to establish the enclave identity. Until an EINIT is executed, the enclave is not permitted to execute any enclave code (i.e. entering the enclave by executing EENTER would result in a fault).

39.1.1 ECREATE

The ECREATE leaf function sets up the initial environment for the enclave by reading an SGX Enclave Control Structure (SECS) that contains the enclave's address range (ELRANGE) as defined by BASEADDR and SIZE, the ATTRIBUTES and MISCSELECT bitmaps, and the SSAFRAMESIZE. It then securely stores this information in an Enclave Page Cache (EPC) page. ELRANGE is part of the application's address space. ECREATE also initializes a cryptographic log of the enclave's build process.

39.1.2 EADD and EEXTEND Interaction

Once the SECS has been created, enclave pages can be added to the enclave via EADD. This involves converting a free EPC page into either a PT_REG or a PT_TCS page.

When EADD is invoked, the processor will update the EPCM entry with the type of page (PT_REG or PT_TCS), the linear address used by the enclave to access the page, and the enclave RWX permissions for the page. It associates the page to the SECS provided as input. The EPCM entry information is used by hardware to manage access control to the page. EADD records EPCM information in the cryptographic log stored in the SECS and copies 4 KBytes of data from unprotected memory outside the EPC to the allocated EPC page.

System software is responsible for selecting a free EPC page. System software is also responsible for providing the type of page to be added, the attributes the page, the contents of the page, and the SECS (enclave) to which the page is to be added as requested by the application. Incorrect data would lead to a failure of EADD or to an incorrect cryptographic log and a failure at EINIT time.

After a page has been added to an enclave, software can measure a 256 byte region as determined by the developer by invoking EEXTEND. Thus to measure an entire 4KB page, system software must execute EEXTEND 16 times. Each invocation of EEXTEND adds to the cryptographic log information about which region is being measured and the measurement of the section.

Entries in the cryptographic log define the measurement of the enclave and are critical in gaining assurance that the enclave was correctly constructed by the un-trusted system software.

39.1.3 EINIT Interaction

Once system software has completed the process of adding and measuring pages, the enclave needs to be initialized by the EINIT leaf function. After an enclave is initialized, EADD and EEXTEND are disabled for that enclave (An attempt to execute EADD/EEXTEND to enclave initialization will result in a fault). The initialization process finalizes the cryptographic log and establishes the **enclave identity** and **sealing identity** used by EGETKEY and EREPORT.

A cryptographic hash of the log is stored as the **enclave identity**. Correct construction of the enclave results in the cryptographic hash matching the one built by the enclave owner and included as the ENCLAVEHASH field of SIGSTRUCT. The **enclave identity** provided by EREPORT can be verified by a remote party.

The EINIT leaf function checks the EINIT token to validate that the enclave has been enabled on this platform. If the enclave is not correctly constructed, or the EINIT token is not valid for the platform, or SIGSTRUCT isn't properly signed, then EINIT will fail. See the EINIT leaf function for details on the error reporting.

The **enclave identity** is a cryptographic hash that reflects the content of the enclave, the order in which it was built, the addresses it occupies in memory, the security attributes, and the MISCSELECT value of each page. The **enclave identity** is established by EINIT.

The **sealing identity** is managed by a sealing authority represented by the hash of the public key used to sign the SIGSTRUCT structure processed by EINIT. The sealing authority assigns a product ID (ISVPRODID) and security version number (ISVSVN) to a particular enclave identity.

EINIT establishes the sealing identity using the following steps:

1. Verifies that SIGSTRUCT is properly signed using the public key enclosed in the SIGSTRUCT.
2. Checks that the measurement of the enclave matches the measurement of the enclave specified in SIGSTRUCT.
3. Checks that the enclave's attributes and MISCSELECT values are compatible with those specified in SIGSTRUCT.
4. Finalizes the measurement of the enclave and records the **sealing identity** (the sealing authority, product id and security version number) and **enclave identity** in the SECS.
5. Sets the ATTRIBUTES.INIT bit for the enclave.

39.2 ENCLAVE ENTRY AND EXITING

39.2.1 Synchronous Entry and Exit

The EENTER leaf function is the method to enter the enclave under program control. To execute EENTER, software must supply an address of a TCS that is part of the enclave to be entered. The TCS holds the location inside the enclave to transfer control to and a pointer to the SSA frame inside the enclave that an AEX should store the register state to.

When a logical processor enters an enclave, the TCS is considered busy until the logical processors exits the enclave. An attempt to enter an enclave through a busy TCS results in a fault. Intel® SGX allows an enclave builder to define multiple TCSs, thereby providing support for multithreaded enclaves.

Software must also supply to EENTER the Asynchronous Exit Pointer (AEP) parameter. AEP is an address external to the enclave which an exception handler will return to using IRET. Typically the location would contain the ERESUME instruction. ERESUME transfers control back to the enclave, to the address retrieved from the enclave thread's saved state.

EENTER performs the following operations:

1. Check that TCS is not busy and flush all caching forms of linear-to-physical mappings.
2. Change the mode of operation to be in enclave mode.
3. Save the old RSP, RBP for later restore on AEX (Software is responsible for setting up the new RSP, RBP).
4. Save XCR0 and replace it with the XFRM value for the enclave.
5. Check if software wishes to debug (applicable to a debuggable enclave):
   - If not debugging, then set hardware so the enclave appears as a single instruction.
   - If debugging, then set hardware to allow traps, breakpoints, and single steps inside the enclave.
6. Set the TCS as busy.
7. Transfer control from outside enclave to predetermined location inside the enclave specified by the TCS.

The EEXIT leaf function is the method of leaving the enclave under program control. EEXIT receives the target address outside of the enclave that the enclave wishes to transfer control to. It is the responsibility of enclave software to erase any secret from the registers prior to invoking EEXIT. To allow enclave software to easily perform an external function call and re-enter the enclave (using EEXIT and EENTER leaf functions), EEXIT returns the value of the AEP that was used when the enclave was entered.

EEXIT performs the following operations:

1. Clear enclave mode and TLB entries for enclave addresses.
2. Mark TCS as not busy.
3. Transfer control from inside the enclave to a location on the outside specified by the register, RBX.

39.2.2 Asynchronous Enclave Exit (AEX)

Asynchronous and synchronous events, such as exceptions, interrupts, traps, SMIs, and VM exits may occur while executing inside an enclave. These events are referred to as Enclave Exiting Events (EEE). Upon an EEE, the processor state is securely saved inside the enclave (in the thread's current SSA frame) and then replaced by a synthetic state to prevent leakage of secrets. The process of securely saving state and establishing the synthetic state is called an Asynchronous Enclave Exit (AEX). Details of AEX is described in Chapter 40, "Enclave Exiting Events".

As part of most EEEs, the AEP is pushed onto the stack as the location of the eventing address. This is the location where control will return to after executing the IRET. The ERESUME leaf function can be executed from that point to reenter the enclave and resume execution from the interrupted point.

After AEX has completed, the logical processor is no longer in enclave mode and the exiting event is processed normally. Any new events that occur after the AEX has completed are treated as having occurred outside the enclave (e.g. a #PF in dispatching to an interrupt handler).

39.2.3 Resuming Execution after AEX

After system software has serviced the event that caused the logical processor to exit an enclave, the logical processor can continue enclave execution using ERESUME. ERESUME restores processor state and returns control to where execution was interrupted.

If the cause of the exit was an exception or a fault and was not resolved, the event will be triggered again if the enclave is re-entered using ERESUME. For example, if an enclave performs a divide by 0 operation, executing ERESUME will cause the enclave to attempt to re-execute the faulting instruction and result in another divide by 0 exception. Intel® SGX provides the means for an enclave developer to handle enclave exceptions from within the enclave. Software can enter the enclave at a different location and invoke the exception handler within the enclave by executing the EENTER leaf function. The exception handler within the enclave can read the fault information from the SSA frame and attempt to resolve the faulting condition or simply return and indicate to software that the enclave should be terminated (e.g. using EEXIT).

39.2.3.1 ERESUME Interaction

ERESUME restores registers depending on the mode of the enclave (32 or 64 bit).

- In 32-bit mode (IA32_EFER.LMA = 0 || CS.L = 0), the low 32-bits of the legacy registers (EAX, EBX, ECX, EDX, ESP, EBP, ESI, EDI, EIP and EFLAGS) are restored from the thread's GPR area of the current SSA frame. Neither the upper 32 bits of the legacy registers nor the 64-bit registers (R8 … R15) are loaded.
- In 64-bit mode (IA32_EFER.LMA = 1 && CS.L = 1), all 64 bits of the general processor registers (RAX, RBX, RCX, RDX, RSP, RBP, RSI, RDI, R8 … R15, RIP and RFLAGS) are loaded.

Extended features specified by SECS.ATTRIBUTES.XFRM are restored from the XSAVE area of the current SSA frame. The layout of the x87 area depends on the current values of IA32_EFER.LMA and CS.L:

- IA32_EFER.LMA = 0 || CS.L = 0
  - — 32-bit load in the same format that XSAVE/FXSAVE uses with these values.
- IA32_EFER.LMA = 1 && CS.L = 1
  - — 64-bit load in the same format that XSAVE/FXSAVE uses with these values plus REX.W = 1.

39.3 CALLING ENCLAVE PROCEDURES

39.3.1 Calling Convention

In standard call conventions subroutine parameters are generally pushed onto the stack. The called routine, being aware of its own stack layout, knows how to find parameters based on compile-time-computable offsets from the SP or BP register (depending on runtime conventions used by the compiler).

Because of the stack switch when calling an enclave, stack-located parameters cannot be found in this manner. Entering the enclave requires a modified parameter passing convention.

For example, the caller might push parameters onto the untrusted stack and then pass a pointer to those parameters in RAX to the enclave software. The exact choice of calling conventions is up to the writer of the edge routines; be those routines hand-coded or compiler generated.

39.3.2 Register Preservation

As with most systems, it is the responsibility of the callee to preserve all registers except that used for returning a value. This is consistent with conventional usage and tends to optimize the number of register save/restore operations that need be performed. It has the additional security result that it ensures that data is scrubbed from any registers that were used to temporarily contain secrets.

39.3.3 Returning to Caller

No registers are modified during EEXIT. It is the responsibility of software to remove secrets in registers before executing EEXIT.

39.4 INTEL® SGX KEY AND ATTESTATION

39.4.1 Enclave Measurement

During the enclave build process, two “measurements” are taken of each enclave and are stored in two 256-bit Measurement Registers (MR): MRENCLAVE and MRSIGNER. MRENCLAVE represents the enclave's contents and build process. MRSIGNER represents the entity that signed the enclave's SIGSTRUCT.

The values of the Measurement Registers are included in attestations to identify the enclave to remote parties. The MRs are also included in most keys, binding keys to enclaves with specific MRs.

39.4.1.1 MRENCLAVE

MRENCLAVE is a unique 256 bit value that identifies the code and data that was loaded into the enclave during the initial launch. It is computed as a SHA256 hash that is initialized by the ECREATE leaf function. EADD and EEXTEND leaf functions record information about each page and the content of those pages. The EINIT leaf function finalizes the hash, which is stored in SECS.MRENCLAVE. Any tampering with the build process, contents of a page, page permissions, etc will result in a different MRENCLAVE value.

Figure 39-2 illustrates a simplified flow of changes to the MRENCLAVE register when building an enclave:

- Enclave creation with ECREATE.
- Copying a non-enclave source page into the EPC of an un-initialized enclave with EADD.
- Updating twice of the MRENCLAVE after modifying the enclave’s page content, i.e. EEXTEND twice.
- Finalizing the enclave build with EINIT.

Details on specific values inserted in the hash are available in the individual instruction definitions.

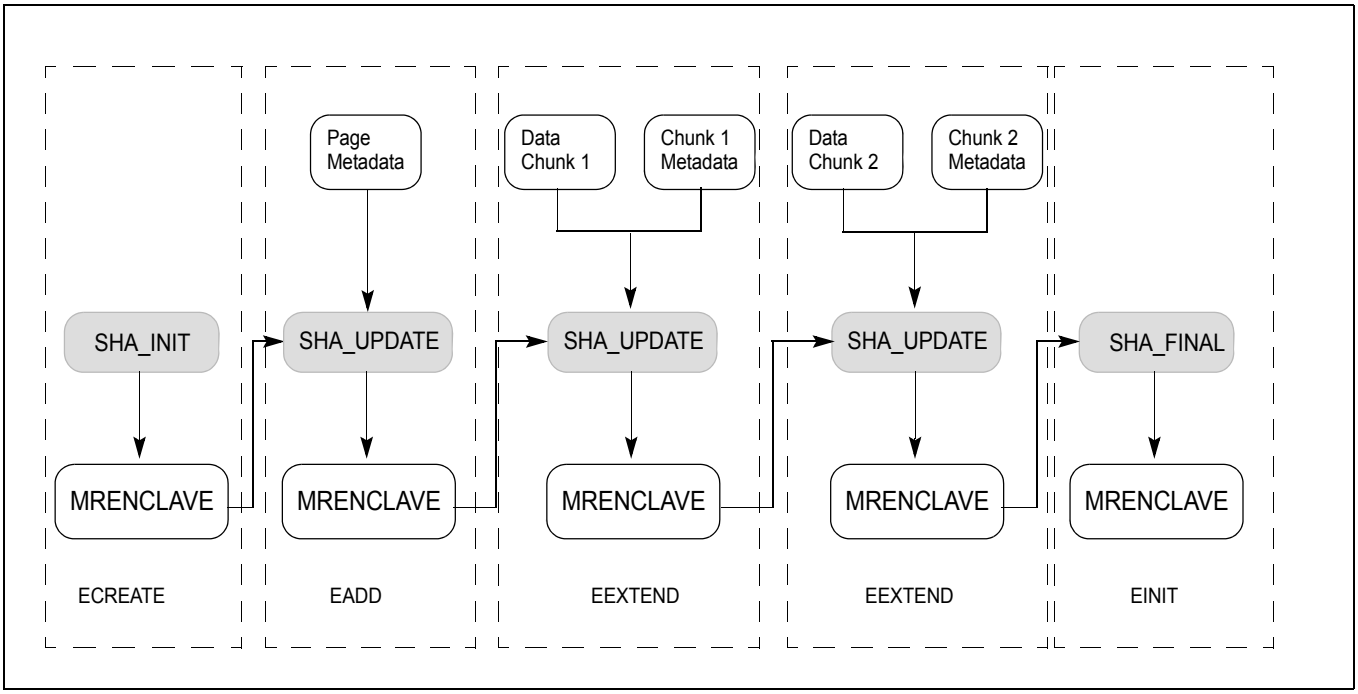

Figure 39-2. Measurement Flow of Enclave Build Process

39.4.1.2 MRSIGNER

Each enclave is signed using a 3072 bit RSA key. The signature is stored in the SIGSTRUCT. In the SIGSTRUCT, the enclave's signer also assigns a product ID (ISVPRODID) and a security version (ISVSVN) to the enclave. MRSIGNER is the SHA-256 hash of the signer's public key.

In attestation, MRSIGNER can be used to allow software to approve of an enclave based on the author rather than maintaining a list of MRENCLAVEs. It is used in key derivation to allow software to create a lineage of an application. By signing multiple enclaves with the same key, the enclaves will share the same keys and data. Combined with security version numbering, the author can release multiple versions of an application which can access keys for previous versions, but not future versions of that application.

39.4.2 Security Version Numbers (SVN)

Intel® SGX supports a versioning system that allows the signer to identify different versions of the same software released by an author. The security version is independent of the functional version an author uses and is intended to specify security equivalence. Multiple releases with functional enhancements may all share the same SVN if they all have the same security properties or posture. Each enclave has an SVN and the underlying hardware has an SVN.

The SVNs are attested to in EREPORT and are included in the derivation of most keys, thus providing separation between data for older/newer versions.

39.4.2.1 Enclave Security Version

In the SIGSTRUCT, the MRSIGNER assigns a 16-bit Product ID (ISVPRODID) and a 16 bit integer SVN (ISVSVN). Together they define a specific group of versions of a specific product. Most keys, including the Seal Key, can be bound to this pair.

To support upgrading from one release to another, EGETKEY will return keys corresponding to any value less than or equal to the software's ISVSVN.

39.4.2.2 Hardware Security Version

CPUSVN is a 128 bit value that reflects the microcode update version and authenticated code modules supported by the processor. Unlike ISVSVN, CPUSVN is not an integer and cannot be compared mathematically. Not all values are valid CPUSVNs.

Software must ensure that the CPUSVN provided to EGETKEY is valid. EREPORT will return the CPUSVN of the current environment. If a local attestation is not in progress, software can execute EREPORT with TARGETINFO set to zeros to retrieve a REPORT. Software can access keys for a CPUSVN recorded previously, provided that each of the elements reflected in CPUSVN are the same or have been upgraded.

39.4.3 Keys

Intel® SGX provides software with access to keys unique to each processor and rooted in HW keys inserted into the processor during manufacturing.

Each enclave requests keys using the EGETKEY leaf function. The key is based on enclave parameters such as measurement, the enclave signing key, security attributes of the enclave, and the TCB of the processor itself. A full list of parameter options is specified in the KEYREQUEST structure, see details in Section 38.17.

By deriving keys using enclave properties, SGX guarantees that if two enclaves call EGETKEY, they will receive a unique key only accessible by the respective enclave. It also guarantees that the enclave will receive the same key on every future execution of EGETKEY. Some parameters are optional or configurable by software. For example, a Seal key can be based on the signer of the enclave, resulting in a key available to multiple enclaves signed by the same party.

The EGETKEY leaf function provides several key types. Each key is specific to the processor, CPUSVN, and the enclave that executed EGETKEY. The EGETKEY instruction definition details how each of these keys is derived, see Table 41-43. Additionally,

- SEAL Key: The Seal key is a general purpose key for the enclave to use to protect secrets. Typical uses of the Seal key are encrypting and calculating MAC of secrets on disk. There are 2 types of Seal Key described in Section 39.4.3.1.
- REPORT Key: This key is used to compute the MAC on the REPORT structure. The EREPORT leaf function is used to compute this MAC, and destination enclave uses the Report key to verify the MAC. The software usage flow is detailed in Section 39.4.3.2.
- LAUNCH Key: This key is used by Launch Enclaves to compute the MAC on EINITTOKENs. These tokens are then verified in the EINIT leaf function. The key is only available to enclaves with ATTRIBUTE.EINITTOKENKEY set to 1.
- PROVISIONING Key and PROVISIONING SEAL Key: These keys are used by attestation key provisioning software to prove to remote parties that the processor is genuine and identify the currently executing TCB. These keys are only available to enclaves with ATTRIB-UTE.PROVISIONKEY set to 1.

39.4.3.1 Sealing Enclave Data

Enclaves can protect persistent data using Seal keys to provide encryption and/or integrity protection. EGETKEY provides two types of Seal keys specified in KEYREQUEST.KEYPOLICY field: MRENCLAVE-based key and MRSIGNER-based key.

The MRENCLAVE-based keys are available only to enclave instances sharing the same MRENCLAVE. If a new version of the enclave is released, the Seal keys will be different. Retrieving previous data requires additional software support.

The MRSIGNER-based keys are bound to the 3 tuple (MRSIGNER, ISVPRODID, ISVSVN). These keys are available to any enclave with the same MRSIGNER and ISVPRODID and an ISVSVN equal to or greater than the key in questions. This is valuable for allowing new versions of the same software to retrieve keys created before an upgrade.

39.4.3.2 Using REPORTs for Local Attestation

SGX provides a means for enclaves to securely identify one another, this is referred to as "Local Attestation". SGX provides a hardware assertion, REPORT that contains calling enclaves Attributes, Measurements and User supplied data (described in detail in Section 38.15). Figure 39-3 shows the basic flow of information.

1. The source enclave determines the identity of the target enclave to populate TARGETINFO.
2. The source enclave calls EREPORT instruction to generate a REPORT structure. The EREPORT instruction conducts the following:
   — Populates the REPORT with identify information about the calling enclave.
   — Derives the Report Key that is returned when the target enclave executes the EGETKEY. TARGETINFO provides information about the target.
   — Computes a MAC over the REPORT.
3. Non-enclave software provides copies the REPORT from source to destination.
4. The target enclave executes the EGETKEY instruction to request its REPORT key, which is the same key used by EREPORT at the source.
5. The target enclave verifies the MAC and can then inspect the REPORT to identify the source.

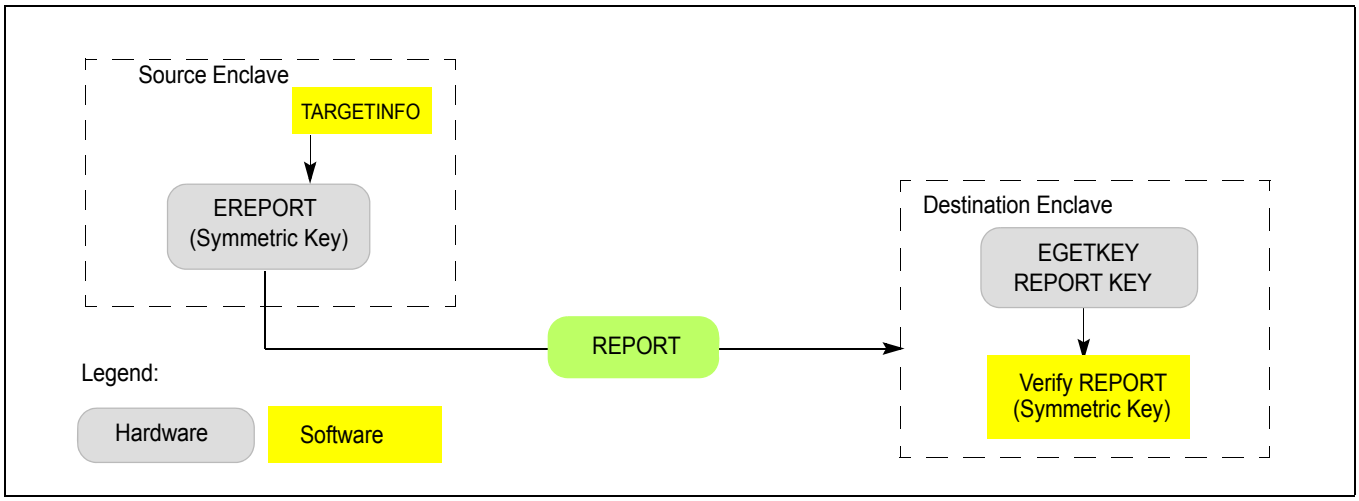

Figure 39-3. SGX Local Attestation

39.5 EPC AND MANAGEMENT OF EPC PAGES

EPC layout is implementation specific, and is enumerated through CPUID (see Table 37-6 for EPC layout). EPC is typically configured by BIOS at system boot time.

39.5.1 EPC Implementation

EPC must be properly protected against attacks. One example of EPC implementation could use a Memory Encryption Engine (MEE). An MEE provides a cost-effective mechanism of creating cryptographically protected volatile storage using platform DRAM. These units provide integrity, replay, and confidentiality protection. Details are implementation specific.

39.5.2 OS Management of EPC Pages

The EPC is a finite resource. SGX1 (i.e. CPUID.(EAX=12H, ECX=0):EAX.SGX1 = 1 but CPUID.(EAX=12H, ECX=0):EAX.SGX2 = 0) provides the EPC manager with leaf functions to manage this resource and properly swap pages out of and into the EPC. For that, the EPC manager would need to keep track of all EPC entries, type and state, context affiliation, and SECS affiliation.

SGX1 includes the EWB leaf function for securely evicting pages out of the EPC. EWB encrypts a page in the EPC, writes it to unprotected memory, and invalidates the copy in EPC. In addition, EWB also creates a cryptographic MAC (PCMD.MAC) of the page and stores it in unprotected memory. A page can be reloaded back to the processor only if the data and MAC match. The version of the evicted page is stored securely in a Version Array (VA) in EPC.

SGX1 includes two instructions for reloading pages that have been evicted by system software: ELDU and ELDB. The difference between the two instructions is the value of the paging state at the end of the instruction. ELDU results in a page being reloaded and set to an UNBLOCKED state, while ELDB results in a page loaded to a BLOCKED state.

ELDB is intended for use by a Virtual Machine Monitor (VMM). When a VMM reloads an evicted page, it needs to restore it to the correct state of the page (BLOCKED vs. UNBLOCKED) as it existed at the time the page was evicted. Based on the state of the page at eviction, the VMM chooses either ELDB or ELDU.

39.5.2.1 Enhancement to Managing EPC Pages

On processors supporting SGX2 (i.e. CPUID.(EAX=12H, ECX=0):EAX.SGX2 = 1), the EPC manager can manage EPC resources (while enclave is running) with more flexibility provided by the SGX2 leaf functions. The additional flexibility is described in Section 39.5.7 through Section 39.5.11.

39.5.3 Eviction of Enclave Pages

Intel SGX paging is optimized to allow the Operating System (OS) to evict multiple pages out of the EPC under a single synchronization.

The suggested flow for evicting a list of pages from the EPC is:

1. For each page to be evicted from the EPC:
   a. Select an empty slot in a Version Array (VA) page.
      - If no empty VA page slots exist, create a new VA page using the EPA leaf function.
   b. Remove linear-address to physical-address mapping from the enclave contexts's mapping tables (page table and EPT tables).
   c. Execute the EBLOCK leaf function for the target page. This sets the target page state to BLOCKED. At this point no new mappings of the page will be created. So any access which does not have the mapping cached in the TLB will generate a #PF.
2. For each enclave containing pages selected in step 1:
   — Execute an ETRACK leaf function pointing to that enclave's SECS. This initiates the tracking process that ensures that all caching of linear-address to physical-address translations for the blocked pages is cleared.
3. For all logical processors executing in processes (OS) or guests (VMM) that contain the enclaves selected in step 1:
   — Issue an IPI (inter-processor interrupt) to those threads. This causes those logical processors to exit any enclaves they might be in, and as a result flush all TLB entries that might hold stale translations to blocked pages. There is no need for additional measures such as performing a "TLB shootdown".
4. After enclaves exit, allow logical processors can resume normal operation, including enclave re-entry as the tracking logic keeps track of the activity.
5. For each page to be evicted:
   — Evict the page using the EWB leaf function with parameters include the effective-address pointer to the EPC page, the VA slot, a 4K byte buffer to hold the encrypted page contents, and a 128 byte buffer to hold page

metadata. The last three elements are tied together cryptographically and must be used to later reload the page.

At this point, system software has the only copy of each page data encrypted with its page metadata in main memory.

39.5.4 Loading an Enclave Page

To reload a previously evicted page, system software needs four elements: the VA slot used when the page was evicted, a buffer containing the encrypted page contents, a buffer containing the page metadata, and the parent SECS to associate this page with. If the VA page or the parent SECS are not already in the EPC, they must be reloaded first.

1. Execute ELDB/ELDU (depending on the desired BLOCKED state for the page)), passing as parameters: the EPC page linear address, the VA slot, the encrypted page, and the page metadata.
2. Create a mapping in the enclave context's mapping tables (page tables and EPT tables) to allow the application to access that page (OS: system page table; VMM: EPT).

The ELDB/ELDU instruction marks the VA slot empty so that the page cannot be replayed at a later date.

39.5.5 Eviction of an SECS Page

The eviction of an SECS page is similar to the eviction of an enclave page. The only difference is that an SECS page cannot be evicted until all other pages belonging to the enclave have been evicted. Since all other pages have been evicted, there will be no threads executing inside the enclave and tracking with ETRACK isn't necessary. When reloading an enclave, the SECS page must be reloaded before all other constituent pages.

1. Ensure all pages are evicted from enclave.
2. Select an empty slot in a Version Array page.
   — If no VA page exists with an empty slot, create a new one using the EPA function leaf.
3. Evict the page using the EWB leaf function with parameters include the effective-address pointer to the EPC page, the VA slot, a 4K byte buffer to hold the encrypted page contents and a 128 byte buffer to hold page metadata. The last three elements are tied together cryptographically and must be used to later reload the page.

39.5.6 Eviction of a Version Array Page

VA pages do not belong to any enclave and tracking with ETRACK isn't necessary. When evicting the VA page, a slot in a different VA page must be specified in order to provide versioning of the evicted VA page.

1. Select a slot in a Version Array page other than the page being evicted.
   — If no VA page exists with an empty slot, create a new one using the EPA leaf function.
2. Evict the page using the EWB leaf function with parameters include the effective-address pointer to the EPC page, the VA slot, a 4K byte buffer to hold the encrypted page contents, and a 128 byte buffer to hold page metadata. The last three elements are tied together cryptographically and must be used to later reload the page.

39.5.7 Allocating a Regular Page

On processors that support SGX2, allocating a new page to an already initialized enclave is accomplished by invoking the EAUG leaf function. Typically, the enclave requests that the OS allocate a new page at a particular location within the enclave's address space. Once allocated, the page remains in a pending state until the enclave executes the corresponding EACCEPT leaf function to accept the new page into the enclave. Page allocation operations may be batched to improve efficiency.

The typical process for allocating a regular page is as follows:

1. Enclave requests additional memory from OS when the current allocation becomes insufficient.
2. The OS invokes the EAUG leaf function to add a new memory page to the enclave.
   a. EAUG may only be called on an invalid page.
   b. Successful completion of the EAUG instruction places the target page in the VALID and PENDING state.
   c. All dynamically created pages have the type PT_REG and content of all zeros.
3. The enclave issues an EACCEPT instruction, which verifies the page's attributes and clears the PENDING state. At that point the page becomes ac-cessible for normal enclave use.

39.5.8 Allocating a TCS Page

On processors that support SGX2, allocating a new TCS page to an already initialized enclave is a two-step process. First the OS allocates a regular page with a call to EAUG. This page must then be accepted and initialized by the enclave to which it belongs. Once the page has been initialized with appropriate values for a TCS page, the enclave requests the OS to change the page's type to PT_TCS. This change must also be accepted. As with allocating a regular page, TCS allocation operations may be batched.

A typical process for allocating a TCS page is as follows:

1. Enclave requests an additional page from the OS.
2. The OS invokes EAUG to add a new regular memory page to the enclave.
   a. EAUG may only be called on an invalid page.
   b. Successful completion of the EAUG instruction places the target page in the VALID and PENDING state.
3. The OS maps the page in the enclave context's mapping tables.
4. The enclave issues an EACCEPT instruction, at which point the page becomes accessible for normal enclave use.
5. The enclave initializes the contents of the new page.
6. The enclave requests that the OS convert the page from type PT_REG to PT_TCS.
7. OS issues an EMODT instruction on the page.
   a. The parameters to EMODT indicate that the regular page should be converted into a TCS.
   b. EMODT forces the RWX bits to 000 because TCS pages may not be accessed by enclave code.
8. The enclave issues an EACCEPT instruction to confirm the requested modification.

39.5.9 Trimming a Page

On processors that support SGX2, Intel SGX supports the trimming of an enclave page as a special case of EMODT. Trimming allows an enclave to actively participate in the process of removing a page from the enclave (dealloca-tion) by splitting the process into first removing it from the enclave's access and then removing it from the EPC using the EREMOVE leaf function. The page type PT_TRIM indicates that a page has been trimmed from the enclave's address space and that the page is no longer accessible to enclave software. Modifications to a page in the PT_TRIM state are not permitted; the page must be removed and then reallocated by the OS before the enclave may use the page again. Page deallocation operations may be batched to improve efficiency.

The typical process for trimming a page from an enclave is as follows:

1. Enclave signals OS that a particular page is no longer in use.
2. OS invokes the EMODT leaf function on the page, requesting that the page's type be changed to PT_TRIM.
   a. SECS and VA pages cannot be trimmed in this way, so the initial type of the page must be PT_REG or PT_TCS.
   b. EMODT may only be called on VALID pages.

3. OS invokes the ETRACK leaf function on the enclave containing the page to track removal the TLB addresses from all the processors.
4. Issue an IPI (inter-processor interrupt) to flush the stale TLB addresses for all logical processors executing in processes (OS) or guests (VMM) that contain the enclave.
5. Enclave issues an EACCEPT leaf function.
6. The OS may now permanently remove the page from the EPC (by issuing EREMOVE).

39.5.10 Restricting the EPCM Permissions of a Page

On processors that support SGX2, restricting the EPCM permissions associated with an enclave page is accomplished using the EMODPR leaf function. This operation requires the cooperation of the OS to flush stale entries to the page and to update the page-table permissions of the page to match. Permissions restriction operations may be batched.

The typical process for restricting the permissions of an enclave page is as follows:

1. Enclave requests that the OS to restrict the permissions of an EPC page.
2. OS performs permission restriction, TLB flushing, and page-table modifications.
    a. Invokes the EMODPR leaf function to restrict permissions (EMODPR may only be called on VALID pages).
    b. Invokes the ETRACK leaf function on the enclave containing the page to track removal of the TLB addresses from all the processor.
    c. Issue an IPI (inter-processor interrupt) to flush the stale TLB addresses for all logical processors executing in processes (OS) or guests (VMM) that contain the enclave.
    d. Sends IPIs to trigger enclave thread exit and TLB shootdown.
    e. OS informs the Enclave that all logical processors should now see the new restricted permissions.
3. Enclave invokes the EACCEPT leaf function.
    a. Enclave may access the page throughout the entire process.
    b. Successful call to EACCEPT guarantees that no stale TLB mappings are present.

39.5.11 Extending the EPCM Permissions of a Page

On processors that support SGX2, extending the EPCM permissions associated with an enclave page is accomplished directly be the enclave using the EMODPE leaf function. After performing the EPCM permission extension, the enclave requests the OS to update the page table permissions to match the extended permission. Security wise, permission extension does not require enclave threads to leave the enclave as TLBs with stale references to the more restrictive permissions will be flushed on demand, but to allow forward progress, an OS needs to be aware that an application might signal a page fault.

The typical process for extending the permissions of an enclave page is as follows:

1. Enclave invokes EMODPE to extend the EPCM permissions associated with an EPC page (EMODPE may only be called on VALID pages).
2. Enclave requests that OS update the page tables to match the new EPCM permissions.
3. Enclave code resumes.
    a. If TLB mappings are present to the more restrictive permissions, the enclave thread will page fault. The SGX2-aware OS will see that the page tables permit the access and resume the thread, which can now successfully access the page because exiting cleared the TLB.
    b. If TLB mappings are not present, access to the page with the new permissions will succeed without an enclave exit.

39.6 CHANGES TO INSTRUCTION BEHAVIOR INSIDE AN ENCLAVE

This section covers instructions whose behavior changes when executed in enclave mode.

39.6.1 Illegal Instructions

The instructions listed in Table 39-1 are ring 3 instructions which become illegal when executed inside an enclave. Executing these instructions inside an enclave will generate a #UD fault.

The first row of Table 39-1 enumerates instructions that may cause a VM exit for VMM emulation. Since a VMM cannot emulate enclave execution, execution of any these instructions inside an enclave results in an invalid-opcode exception (#UD) and no VM exit.

The second row of Table 39-1 enumerates I/O instructions that may cause a fault or a VM exit for emulation. Again, enclave execution cannot be emulated, so execution of any these instructions inside an enclave results in #UD.

The third row of Table 39-1 enumerates instructions that load descriptors from the GDT or the LDT or that change privilege level. The former class is disallowed because enclave software should not depend on the contents of the descriptor tables and the latter because enclave execution must be entirely with CPL = 3. Again, execution of any these instructions inside an enclave results in #UD.

The fourth row of Table 39-1 enumerates instructions that provide access to kernel information from user mode and can be used to aid kernel exploits from within enclave. Execution of any these instructions inside an enclave results in #UD

Table 39-1. Illegal Instructions Inside an Enclave

Instructions	Result	Comment
CPUID, GETSEC, RDPMC, SGDT, SIDT, SLDT, STR, VMCALL, VMFUNC	#UD	Might cause VM exit.
IN, INS/INSB/INSW/INSD, OUT, OUTS/OUTSB/OUTSW/OUTSD	#UD	I/O fault may not safely recover. May require emulation.
Far call, Far jump, Far Ret, INT n/INTO, IRET, LDS/LES/LFS/LGS/LSS, MOV to DS/ES/SS/FS/GS, POP DS/ES/SS/FS/GS, SYSCALL, SYSENTER	#UD	Access segment register could change privilege level.
LAR, VERR, VERW, SMSW	#UD	Might provide access to kernel information.
ENCLU[EENTER], ENCLU[ERESUME]	#GP	Cannot enter an enclave from within an enclave.

RDTSC and RDTSCP instructions are legal instructions inside an enclave.

RDTSC and RDTSCP instructions are legal instructions inside an enclave subject to the value of CR4. TSD.

RDTSC and RDTSCP instructions may cause a VM exit when inside an enclave.

Software developers must take into account that the RDTSC/RDTSCP results are not immune to influences by other software, e.g. the TSC can be manipulated by software outside the enclave.

NOTE

Some early processor implementation of Intel SGX will generate a #UD when RDTSC and RDTSCP are executed inside an enclave. See the model-specific processor errata for details of which processors treat execution of RDTSC and RDTSCP inside an enclave as illegal.

39.6.2 RDRAND and RDSEED Instructions

These instructions may cause a VM exit if the "RDRAND exiting" VM-execution control is 1. Unlike other instructions that can cause VM exits, these instructions are legal inside an enclave. As noted in Section 6.5.5, any VM exit originating on an instruction boundary inside an enclave sets bit 27 of the exit-reason field of the VMCS. If a VMM receives a VM exit due to an attempt to execute either of these instructions determines (by that bit) that the execution was inside an enclave, it can do either of two things. It can clear the "RDRAND exiting" VM-execution control and execute VMRESUME; this will result in the enclave executing RDRAND or RDSEED again, and this time a VM exit will not occur. Alternatively, the VMM might choose to discontinue execution of this virtual machine.

NOTE

It is expected that VMMs that virtualize Intel SGX will not set "RDRAND exiting" to 1.

39.6.3 PAUSE Instruction

The PAUSE instruction may cause a VM exit if either of the "PAUSE exiting" and "PAUSE-loop exiting" VM-execution controls is 1. Unlike other instructions that can cause VM exits, the PAUSE instruction is legal inside an enclave.

If a VMM receives a VM exit due to the 1-setting of "PAUSE-loop exiting", it may take action to prevent recurrence of the PAUSE loop (e.g., by scheduling another virtual CPU of this virtual machine) and then execute VMRESUME; this will result in the enclave executing PAUSE again, but this time the PAUSE loop (and resulting VM exit) will not occur.

If a VMM receives a VM exit due to the 1-setting of "PAUSE exiting", it can do either of two things. It can clear the "PAUSE exiting" VM-execution control and execute VMRESUME; this will result in the enclave executing PAUSE again, but this time a VM exit will not occur. Alternatively, the VMM might choose to discontinue execution of this virtual machine.

NOTE

It is expected that VMMs that virtualize Intel SGX will not set "PAUSE exiting" to 1.

39.6.4 INT 3 Behavior Inside an Enclave

INT3 is legal inside an enclave, however, the behavior inside an enclave is different from its behavior outside an enclave. See Section 43.4.1 for details.

39.6.5 INVD Handling when Enclaves Are Enabled

Once processor reserved memory protections are activated (see Section 39.5), any execution of INVD will result in a #GP(0).

CHAPTER 40
ENCLAVE EXITING EVENTS

Certain events, such as exceptions and interrupts, incident to (but asynchronous with) enclave execution may cause control to transition to an address outside the enclave. (Most of these also cause a change of privilege level.) To protect the integrity and security of the enclave, the processor will exit the enclave (and enclave mode) before invoking the handler for such an event. For that reason, such events are called an **enclave-exiting events** (EEE); EEEs include external interrupts, non-maskable interrupts, system-management interrupts, exceptions, and VM exits.

The process of leaving an enclave in response to an EEE is called an **asynchronous enclave exit** (AEX). To protect the secrecy of the enclave, an AEX saves the state of certain registers within enclave memory and then loads those registers with fixed values called **synthetic state**.

40.1 COMPATIBLE SWITCH TO THE EXITING STACK OF AEX

Asynchronous enclave exits push information onto the appropriate stack in a form expected by the operating system. To accomplish this, an address to trampoline code outside of the enclave is pushed onto the exiting stack as the returning RIP. This trampoline code eventually returns to the enclave by means of an ENCLU(ERESUME) leaf function. Prior to exiting the enclave the RSP and RBP registers are restored to their values prior to enclave entry.

The stack to be used is chosen using the same rules as for non-SGX mode:

- If there is a privilege level change, the stack will be the one associated with the new ring.
- If there is no privilege level change, the current application stack is used.
- If the IA-32e IST mechanism is used, the exit stack is chosen using that method.

In all cases, the choice of exit stack and the information pushed onto it is consistent with non-SGX operation. Figure 40-1 shows the Application and Exiting Stacks after an exit with a stack switch. An exit without a stack switch uses the Application Stack. The ERESUME leaf index value is placed into RAX, the TCS pointer is placed in RBX and the AEP (see below) is placed into RCX to facilitate resuming the enclave after the exit.

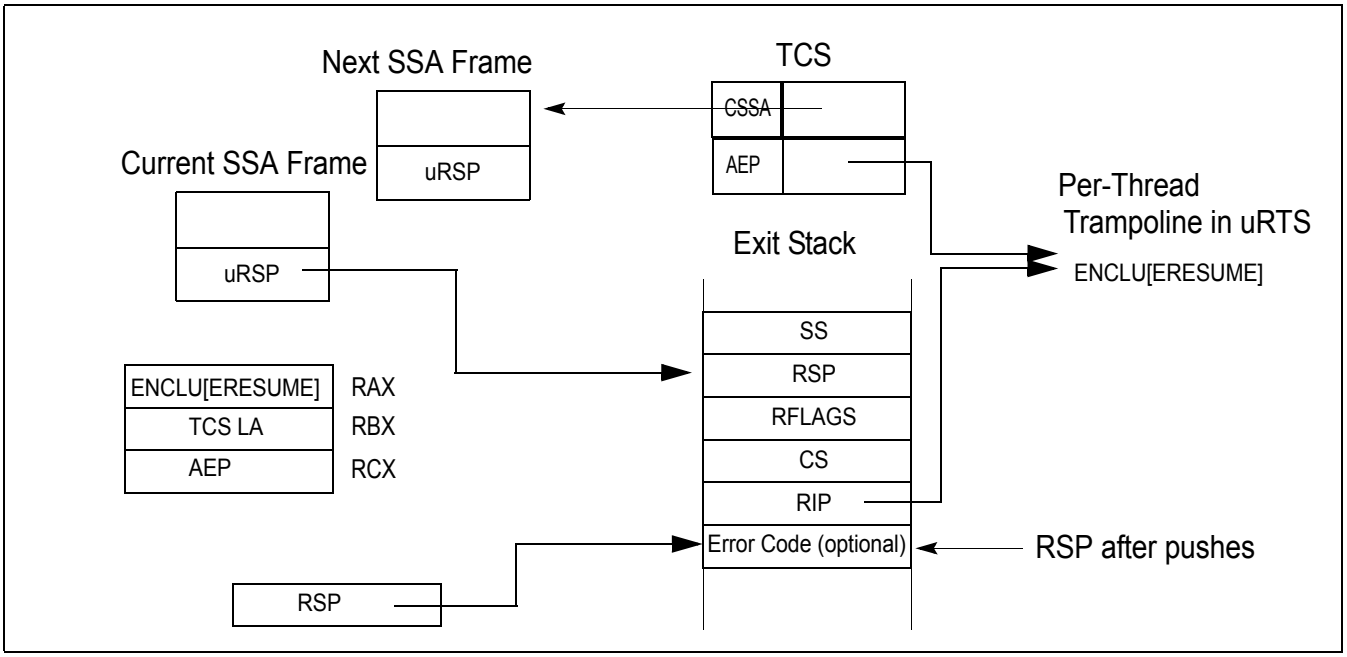

Figure 40-1. Exit Stack Just After Interrupt with Stack Switch

Upon an AEX, the AEP (Asynchronous Exit Pointer) is pushed onto the exit stack as the return RIP. The AEP points to a trampoline code sequence which includes the ERESUME instruction that is later used to reenter the enclave.

The following bits of RFLAGS are cleared before RFLAGS is pushed onto the exit stack: CF, PF, AF, ZF, SF, OF, RF. The remaining bits are left unchanged.

40.2 STATE SAVING BY AEX

The State Save Area holds the processor state at the time of an AEX. To allow handling events within the enclave and re-entering it after an AEX, the SSA can be a stack of multiple SSA frames as illustrated in Figure 40-2.

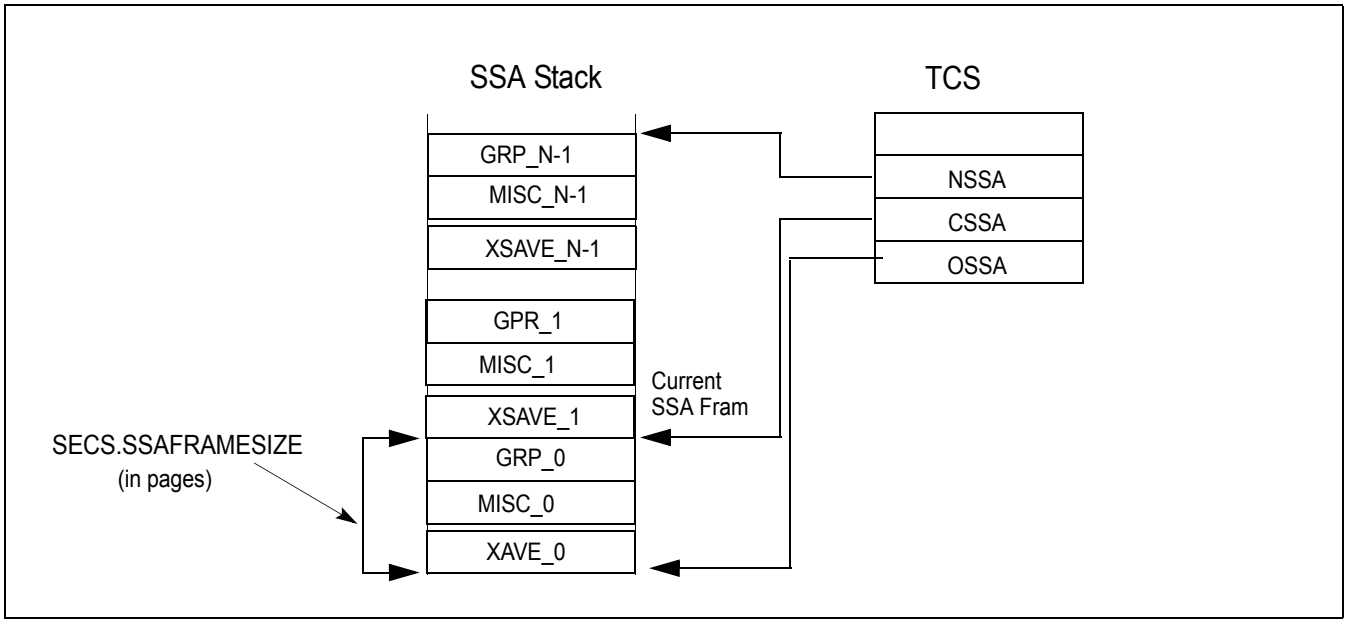

Figure 40-2. The SSA Stack

The location of the SSA frames to be used is controlled by the following variables in the TCS and the SECS:

- Size of a frame in the State Save Area (SECS.SSAFRAMESIZE). Defines the number of 4K byte pages in a single frame in the State Save Area. Must be large enough to hold the GPR state, the XSAVE state, and the MISC state.
- Base address of the enclave (SECS.BASEADDR). Defines the enclave's base linear address from which the offset to the base of the SSA stack is calculated.
- Number of State Save Area Slots (TCS.NSSA). Defines the total number of slots (frames) in the State Save Area stack.
- Current State Save Area Slot (TCS.CSSA). Defines the current slot to use on the next exit.
- State Save Area (TCS.OSSA). Defines the offset of the base address of a set of State Save Area slots from the enclave’s base address.

When an AEX occurs while executing on a thread inside the enclave, hardware selects the SSA frame to use by examining TCS.CSSA. Processor state (as described in Section 40.3.1) is saved into the SSA frame and loaded with a synthetic state (to avoid leaking secrets), RSP and RP are restored to their values prior to enclave entry, and TCS.CSSA is incremented. As will be described later, if an exception takes the last slot, it will not be possible to reenter the enclave to handle the exception from within the enclave.

The format of the XSAVE section of SSA is identical to the format used by the XSAVE/XRSTOR instructions. On EENTER, CSSA must be less than NSSA, ensuring that there is at least one State Save Area slot available for exits.

Multiple SSA frames allow for handling a variety of situations. For example,

- When an AEX occurs the SSA frame is loaded and the pointer incremented.

- An ERESUME restores the processor state and frees the SSA frame.
- If after the AEX an EENTER is executed then the next SSA frame is reserved to hold state for another AEX.

If there is no free SSA frame when executing EENTER, the entry will fail.

40.3 SYNTHETIC STATE ON ASYNCHRONOUS ENCLAVE EXIT

40.3.1 Processor Synthetic State on Asynchronous Enclave Exit

Table 40-1 shows the synthetic state loaded on AEX. The values shown are the lower 32 bits when the processor is in 32 bit mode and 64 bits when the processor is in 64 bit mode.

Table 40-1. GPR, x87 Synthetic States on Asynchronous Enclave Exit

Register	Value
RAX	3 (ENCLU[3] is ERESUME).
RBX	Pointer to TCS of interrupted enclave thread.
RCX	AEP of interrupted enclave thread.
RDX, RSI, RDI	0.
RSP	Restored from SSA.uRSP.
RBP	Restored from SSA.uRBP.
R8-R15	0 in 64-bit mode; unchanged in 32-bit mode.
RIP	AEP of interrupted enclave thread.
RFLAGS	CF, PF, AF, ZF, SF, OF, RF bits are cleared. All other bits are left unchanged.
x87/SSE State	Unless otherwise listed here, all x87 and SSE state are set to the INIT state. The INIT state is the state that would be loaded by the XRSTOR instruction with bits 1:0 both set in the requested feature bitmask (RFBM), and both clear in XSTATE_BV the XSAVE header.
FCW	On #MF exception: set to 037EH. On all other exits: set to 037FH.
FSW	On #MF exception: set to 8081H. On all other exits: set to 0H.
MXCSR	On #XM exception: set to 1F01H. On all other exits: set to 1FB0H.
CR2	If the event that caused the AEX is a #PF, and the #PF does not directly cause a VM exit, then the low 12 bits are cleared. If the #PF leads directly to a VM exit, CR2 is not updated (usual IA behavior). Note: The low 12 bits are not cleared if a #PF is encountered during the delivery of the EEE that caused the AEX. This is because it is the AEX that clears those bits, and EEE delivery occurs after AEX.
FS, GS	Restored to values as of most recent EENTER/ERESUME.

40.3.2 Synthetic State for Extended Features

When CR4.OSXSAVE = 1, extended features (those controlled by XCR0[63:2]) are set to their respective INIT states when this corresponding bit of SECS.XFRM is set. The INIT state is the state that would be loaded by the XRSTOR instruction had the instruction mask and the XSTATE_BV field of the XSAVE header each contained the value XFRM. (When the AEX occurs in 32-bit mode, those features that do not exist in 32-bit mode are unchanged.)

40.3.3 Synthetic State for MISC Features

State represented by SECS.MISCSELECT might also be overridden by synthetic state after it has been saved into the SSA. State represented by MISCSELECT[0] doesn't need to be overridden as it isn't accessible to software.

40.3.4 VMCS Synthetic State on Asynchronous Enclave Exit

All processor registers saved in the VMCS have the same synthetic values listed above. Additional VMCS fields that are treated specially on VM exit are listed in Table 40-2

Table 40-2. VMCS Synthetic States on Asynchronous Enclave Exit

VMCS Field	Position	Value
ENCLAVE_INTERRUPTION in "Guest Interruptibility State"	4	Set to 1 to enable Guest Interruptibility State in enclave mode.
ENCLAVE_INTERRUPTION in "Basic VM-exit information"	27	Set to 1 if VM exit occurred in enclave mode.
Guest-linear address		If the event that caused the AEX is an EPT violation that sets bit 7 of the Exit-Qualification field, the low 12 bits of Guest-linear address field is cleared. Note: If the EPT violation occurs during delivery of an event that caused the AEX (e.g., an EPT violation that occurs during IDT-vectoring), then the low 12 bits are NOT cleared.
Guest-physical address		If the event that caused the AEX is an EPT violation or mis-configured EPT, then the low 12 bits of Guest-physical address field is cleared. Note: If the EPT violation or misconfiguration occurs during delivery of an event that caused the AEX (e.g., an EPT violation or misconfiguration that occurs during IDT-vectoring), then the low 12 bits are NOT cleared.
Exit-Qualification		On page-fault that causes an AEX: low 12 bits are cleared. On APIC-access that causes an AEX: low 12 bits are cleared. Note: If either the page-fault or APIC-access occurs during delivery of an event that caused the AEX, the low 12 bits are NOT cleared.
VM-exit instruction length		Cleared.
VM-exit instruction information		This field is defined only for VM exits due to the execution of specific instructions. The instructions that cause VM exits when executed inside an enclave include: MOV DR, INVEPT, INVVPID, RDTSC, RDTSCP, VMCLEAR, VMLAUNCH, VMPTRLD, VMPTRST, VMREAD, VMRESUME, VMWRITE, VMXOFF, and VMXON. Normally, this field is defined for VM exits due to INT3 (or exceptions encountered while delivering INT3). This is not true for INT3 in an enclave, as the instruction becomes fault-like. INT3 Interruption types are reported as hardware exception when invoked inside enclave instead of 6 respectively when invoked outside enclave. This field is cleared for all other VM exits.
I/O RCX		Cleared.
I/O RSI		Cleared.
I/O RDI		Cleared.
I/O RIP		Cleared.

40.4 AEX FLOW

On Enclave Exiting Events (interrupts, exceptions, VM exits or SMIs), the processor state is securely saved inside the enclave, a synthetic state is loaded and the enclave is exited. The EEE then proceeds in the usual exit-defined fashion. The following sections describes the details of an AEX:

1. The exact processor state saved into the current SSA frame depends on whether the enclave is a 32-bit or a 64-bit enclave. In 32-bit mode (IA32_EFER.LMA = 0 || CS.L = 0), the low 32 bits of the legacy registers (EAX, EBX, ECX, EDX, ESP, EBP, ESI, EDI, EIP and EFLAGS) are stored. The upper 32 bits of the legacy registers and the 64-bit registers (R8 … R15) are not stored.

   In 64-bit mode (IA32_EFER.LMA = 1 && CS.L = 1), all 64 bits of the general processor registers (RAX, RBX, RCX, RDX, RSP, RBP, RSI, RDI, R8 … R15, RIP and RFLAGS) are stored.

The state of those extended features specified by SECS.ATTRIBUTES.XFRM are stored into the XSAVE area of the current SSA frame. The layout of the x87 and XMM portions (the 1st 512 bytes) depends on the current values of IA32_EFER.LMA and CS.L:

If IA32_EFER.LMA = 0 || CS.L = 0, the same format (32-bit) that XSAVE/FXSAVE uses with these values.

If IA32_EFER.LMA = 1 && CS.L = 1, the same format (64-bit) that XSAVE/FXSAVE uses with these values when REX.W = 1.

The state of those miscellaneous features specified by SECS.MISCSELECT are stored into the MISC area of the current SSA frame.

2. Synthetic state is created for a number of processor registers to present an opaque view of the enclave state. Table 40-1 shows the values for GPRs, x87, SSE, FS, GS, Debug and performance monitoring on AEX. The synthetic state for other extended features (those controlled by XCR0[62:2]) is set to their respective INIT states when their corresponding bit of SECS.ATTRIBUTES.XFRM is set. The INIT state is that state as defined by the behavior of the XRSTOR instruction when HEADER.XSTATE_BV[n] is 0. In addition, on VM exit the VMCS or SMRAM state is initialized as described in Table 40-2. Synthetic state of those miscellaneous features specified by SECS.MISCSELECT depends on the miscellaneous feature. There is no synthetic state required for the miscellaneous state controlled by SECS.MISCSELECT[0].
3. In the current SSA frame, the cause of the AEX is saved in the EXITINFO field. See Table 38-9 for details and values of the various fields.
4. Any code and data breakpoints that were suppressed at the time of enclave entry are unsuppressed when exiting the enclave.
5. RFLAGS.TF is set to the value that it had at the time of the most recent enclave entry (except for the situation that the entry was opt-in for debug; see Section 43.2). In the SSA, RFLAGS.TF is set to 0.
6. RFLAGS.RF is set to 0 in the synthetic state. In the SSA, the value saved is the same as what would have been saved on stack in the non-SGX case (architectural value of RF). Thus, AEXs due to interrupts, traps, and code breakpoints save RF unmodified into SSA, while AEXs due to other faults save RF as 1 in the SSA.

   If the event causing AEX happened on intermediate iteration of a REP-prefixed instruction, then RF=1 is saved on SSA, irrespective of its priority.
7. Any performance monitoring activity (including PEBS) or profiling activity (LBR, Tracing using Intel PT) on the exiting thread that was suppressed due to the enclave entry on that thread is unsuppressed. Any counting that had been demoted from AnyThread counting to MyThread counting (on one logical processor) is promoted back to AnyThread counting.

40.4.1 AEX Operational Detail

Temp Variables in AEX Operational Flow

Name	Type	Size (bits)	Description
TMP_RIP	Effective Address	32/64	Address of instruction at which to resume execution on ERESUME.
TMP_MODE64	binary	1	((IA32_EFER.LMA = 1) && (CS.L = 1)).
TMP_BRANCH_RECORD	LBR Record	2x64	From/To address to be pushed onto LBR stack.

The pseudo code in this section describes the internal operations that are executed when an AEX occurs in enclave mode. These operations occur just before the normal interrupt or exception processing occurs.

```
(* Save RIP for later use *)
TMP_RIP = Linear Address of Resume RIP
(* Is the processor in 64-bit mode? *)
TMP_MODE64 ← ((IA32_EFER.LMA = 1) && (CS.L = 1));

(* Save all registers, When saving EFLAGS, the TF bit is set to 0 and
```

```
    the RF bit is set to what would have been saved on stack in the non-SGX case *)

 IF (TMP_MODE64 = 0)
    THEN
        Save EAX, EBX, ECX, EDX, ESP, EBP, ESI, EDI, EFLAGS, EIP into the current SSA frame using
CR_GPR_PA; (* see Table 41-4 for list of CREGs used to describe internal operation within Intel SGX *)
        SSA.RFLAGS.TF ← 0;
    ELSE    (* TMP_MODE64 = 1 *)
        Save RAX, RBX, RCX, RDX, RSP, RBP, RSI, RDI, R8-R15, RFLAGS, RIP into the current SSA frame using
CR_GPR_PA;
        SSA.RFLAGS.TF ← 0;
FI;
Save FS and GS BASE into SSA using CR_GPR_PA;

(* store XSAVE state into the current SSA frame's XSAVE area using the physical addresses
    that were determined and cached at enclave entry time with CR_XSAVE_PAGE_i. *)
For each XSAVE state i defined by (SECS.ATTRIBUTES.XFRM[i] = 1, destination address cached in
CR_XSAVE_PAGE_i)
   SSA.XSAVE.i ← XSAVE_STATE_i;

(* Clear bytes 8 to 23 of XSAVE_HEADER, i.e. the next 16 bytes after XHEADER_BV *)

CR_XSAVE_PAGE_0.XHEADER_BV[191:64] ← 0;

(* Clear bits in XHEADER_BV[63:0] that are not enabled in ATTRIBUTES.XFRM *)

CR_XSAVE_PAGE_0.XHEADER_BV[63:0] ←
    CR_XSAVE_PAGE_0.XHEADER_BV[63:0] & SECS(CR_ACTIVE_SECS).ATTRIBUTES.XFRM;
    Apply synthetic state to GPRs, RFLAGS, extended features, etc.

(* Restore the RSP and RBP from the current SSA frame's GPR area using the physical address
    that was determined and cached at enclave entry time with CR_GPR_PA. *)
RSP ← CR_GPR_PA.URSP;
RBP ← CR_GPR_PA.URBP;

(* end_of_flow *)
(* Execution continues with normal event processing. *)
```

CHAPTER 41
SGX INSTRUCTION REFERENCES

This chapter describes the supervisor and user level instructions provided by Intel® Software Guard Extensions (Intel® SGX). In general, a various functionality is encoded as leaf functions within the ENCLS (supervisor) and ENCLU (user) instruction mnemonics. Different leaf functions are encoded by specifying an input value in the EAX register of the respective instruction mnemonic.

41.1 INTEL® SGX INSTRUCTION SYNTAX AND OPERATION

ENCLS and ENCLU instruction mnemonics for all leaf functions are covered in this section.

For all instructions, the value of CS.D is ignored; addresses and operands are 64 bits in 64-bit mode and are otherwise 32 bits. Aside from EAX specifying the leaf number as input, each instruction leaf may require all or some subset of the RBX/RCX/RDX as input parameters. Some leaf functions may return data or status information in one or more of the general purpose registers.

41.1.1 ENCLS Register Usage Summary

Table 41-1 summarizes the implicit register usage of supervisor mode enclave instructions.

Table 41-1. Register Usage of Privileged Enclave Instruction Leaf Functions

41.1.3 Information and Error Codes

Information and error codes are reported by various instruction leaf functions to show an abnormal termination of the instruction or provide information which may be useful to the developer. Table 41-3 shows the various codes and the instruction which generated the code. Details of the meaning of the code is provided in the individual instruction.

Table 41-3. Error or Information Codes for Intel® SGX Instructions

41.1.4 Internal CREGs

The CREGs as shown in Table 5-4 are hardware specific registers used in this document to indicate values kept by the processor. These values are used while executing in enclave mode or while executing an Intel SGX instruction. These registers are not software visible and are implementation specific. The values in Table 41-4 appear at various places in the pseudo-code of this document. They are used to enhance understanding of the operations.

Table 41-4. List of Internal CREG

Name	Size (Bits)	Scope

41.1.5 Concurrent Operation Restrictions

To protect the integrity of Intel SGX data structures, under certain conditions, Intel SGX disallows certain leaf functions from operating concurrently. Listed below are some examples of concurrency that are not allowed.

- For example, Intel SGX disallows the following leafs to concurrently operate on the same EPC page.
  - ECREATE, EADD, and EREMOVE are not allowed to operate on the same EPC page concurrently with themselves.
  - EADD, EEXTEND, and EINIT leafs are not allowed to operate on the same SECS concurrently.
- Intel SGX disallows the EREMOVE leaf from removing pages from an enclave that is in use.
- Intel SGX disallows entry (EENTER and ERESUME) to an enclave while a page from that enclave is being removed.

When disallowed operation is detected, a leaf function causes an exception. To prevent such exceptions, software must serialize leaf functions or prevent these leaf functions from accessing the same resource.

41.1.5.1 Concurrency Table of Intel® SGX Instructions

Concurrent restriction of an individual leaf function (ENCLS or ENCLU) with another Intel SGX instruction leaf functions is listed under the **Concurrency Restriction** paragraph of the respective reference pages of the leaf function.

The concurrency restriction depends on the type of EPC page and the parameter of the two concurrent instructions each Intel SGX instruction leaf attempts to operate on. The spectrum concurrency behavior of the instruction leaf shown in a given row is denoted by the following:

- 'N': The instructions listed in a given row heading may not execute concurrently with the instruction leaf shown in the respective column. Software should serialize them.
- 'Y': The instruction leaf listed in a given row may execute concurrently with the instruction leaf shown in the respective column.
- 'C': The instruction leaf listed in a given row heading may return an error code when executed concurrently with the instruction leaf shown in the respective column.
- 'U': These two instruction leaves may complete, but the occurrence these two simultaneous flows are considered a user program error for which the processor does not enforce any restriction.
- A grey cell indicates concurrent execution of two leaf functions that is architecturally impossible or restricted, e.g. executing an ENCLU and an ENCLS leaf on the same logical processor, or executing two leaves with incompatible EPCM state requirements. Concurrent execution of two such leaf instructions may result in a page fault in one of the leaf instructions.

For instance, multiple ELDB/ELDUs are allowed to execute as long as the selected EPC page is not the same page. Multiple ETRACK operations are not allowed to execute concurrently.

41.2 INTEL® SGX INSTRUCTION REFERENCE

ENCLS—Execute an Enclave System Function of Specified Leaf Number

Opcode/ Instruction	Op/En	64/32 bit Mode Support	CPUID Feature Flag	Description
0F 01 CF ENCLS	NP	V/V	SGX1	This instruction is used to execute privileged Intel SGX leaf functions that are used for managing and debugging the enclaves.

Instruction Operand Encoding

Op/En	Operand 1	Operand 2	Operand 3	Implicit Register Operands
NP	NA	NA	NA	See Section 41.3

Description

The ENCLS instruction invokes the specified privileged Intel SGX leaf function for managing and debugging enclaves. Software specifies the leaf function by setting the appropriate value in the register EAX as input. The registers RBX, RCX, and RDX have leaf-specific purpose, and may act as input, as output, or may be unused. In 64-bit mode, the instruction ignores upper 32 bits of the RAX register.

The instruction also results in a #UD if CR0.PE is 0 or RFLAGS.VM is 1, or if it is executed from in SMM mode. Additionally, any attempt to execute this instruction when current privilege level is not 0 results in #UD.

Any attempt to invoke an undefined leaf function results in #GP(0).

If CR0.PG is 0, any attempt to execute ENCLS results in #GP(0).

In VMX non-root operation, execution of ENCLS is unconditionally allowed if the "Enable ENCLS exiting" VM-execution control is cleared. If the "Enable ENCLS exiting" VM-execution control is set, execution of individual leaf function of ENCLS is governed by the "ENCLS-exiting bitmap". Each bit position of "ENCLS-exiting bitmap" corresponds to the index (EAX) of an ENCLS leaf function.

Software in VMX root mode of operation can intercept the invocation of various ENCLS leaf functions from VMX non-root mode by setting the Enable_ENCLS_EXITING control and writing the desired bit patterns into the "ENCLS-exiting bitmap" (accessed via encoding pair 0202EH/0202FH). A processor implements the Enable_ENCLS_EXITING VM-execution control field if IA32_VMX_PROCBASED_CTLS2[15] is read as 1.

The DS segment is used to create linear addresses.

Addresses and operands are 32 bits outside 64-bit mode (IA32_EFER.LMA = 0 || CS.L = 0) and are 64 bits in 64-bit mode (IA32_EFER.LMA = 1 || CS.L = 1). CS.D value has no impact on address calculation.

Segment prefix override is ignored. Address size prefix (67H) override is ignored.

REX prefix is ignored in 64-bit mode.

Operation

```
IN_64BIT_MODE← 0;
IF TSX_ACTIVE
    Then GOTO TSX_ABORT_PROCESSING; FI;

IF ( CR0.PE = 0 or RFLAGS.VM = 1 or IN_SMM or CPUID.SGX_LEAF.0:EAX.SE1 = 0 )
    Then #UD; FI;

IF (CPL > 0)
    Then #UD; FI;

IF ( (in VMX non-root operation) and ( Enable_ENCLS_EXITING = 1) )
    Then
        IF ( ((EAX < 63) and (ENCLS_EXITING_Bitmap[EAX] = 1)) or (EAX> 62 and ENCLS_EXITING_Bitmap[63] = 1) )
            Then
            Set VMCS.EXIT_REASON = ENCLS;
```

```
                Deliver VM exit;
            FI;
FI;
IF (IA32_FEATURE_CONTROL.LOCK = 0 or IA32_FEATURE_CONTROL.SGX_ENABLE = 0)
    Then #GP(0); FI;

IF (EAX is invalid leaf number)
    Then #GP(0); FI;

IF (CR0.PG = 0)
    Then #GP(0); FI;

IN_64BIT_MODE ← IA32_EFER.LMA AND CS.L ? 1 : 0;

( * DS must not be an expanded down segment *)
IF (IN_64BIT_MODE = 0 and (DS[S] = 1) and (DS[bit 11] = 0) and DS[bit 10] = 1)
    Then #GP(0); FI;

Jump to leaf specific flow
```

Flags Affected

See individual leaf functions

Protected Mode Exceptions

#UD	If any of the LOCK/OSIZE/REP/VEX prefix is used.
	If current privilege level is not 0.
	If CPUID.(EAX=12H,ECX=0):EAX.SGX1 [bit 0] = 0.
	If logical processor is in SMM.
#GP(0)	If IA32_FEATURE_CONTROL.LOCK = 0.
	If IA32_FEATURE_CONTROL.SGX_ENABLE = 0.
	If input value in EAX encodes an unsupported leaf.
	If data segment expand down.
	If CR0.PG=0.

Real-Address Mode Exceptions

#UD	ENCLS is not recognized in real mode.

Virtual-8086 Mode Exceptions

#UD	ENCLS is not recognized in virtual-8086 mode.

Compatibility Mode Exceptions

Same exceptions as in protected mode.

64-Bit Mode Exceptions

#UD	If any of the LOCK/OSIZE/REP/VEX prefix is used.
	If current privilege level is not 0.
	If CPUID.(EAX=12H,ECX=0):EAX.SGX1 [bit 0] = 0.
	If logical processor is in SMM.
#GP(0)	If IA32_FEATURE_CONTROL.LOCK = 0.
	If IA32_FEATURE_CONTROL.SGX_ENABLE = 0.
	If input value in EAX encodes an unsupported leaf.

ENCLU—Execute an Enclave User Function of Specified Leaf Number

Opcode/ Instruction	Op/En	64/32 bit Mode Support	CPUID Feature Flag	Description
0F 01 D7 ENCLU	NP	V/V	SGX1	This instruction is used to execute non-privileged Intel SGX leaf functions.

Instruction Operand Encoding

Op/En	Operand 1	Operand 2	Operand 3	Implicit Register Operands
NP	NA	NA	NA	See Section 41.4

Description

The ENCLU instruction invokes the specified non-privileged Intel SGX leaf functions. Software specifies the leaf function by setting the appropriate value in the register EAX as input. The registers RBX, RCX, and RDX have leaf-specific purpose, and may act as input, as output, or may be unused. In 64-bit mode, the instruction ignores upper 32 bits of the RAX register.

The instruction also results in a #UD if CR0.PE is 0 or RFLAGS.VM is 1, or if it is executed from inside SMM. Additionally, any attempt to execute this instruction when current privilege level is not 3 results in #UD.

Any attempt to invoke an undefined leaf function results in #GP(0).

Any attempt to execute ENCLU instruction when paging is disabled or in MS-DOS compatible mode results in #GP.

The DS segment is used to create linear addresses.

Addresses and operands are 32 bits outside 64-bit mode (IA32_EFER.LMA = 0 || CS.L = 0) and are 64 bits in 64-bit mode (IA32_EFER.LMA = 1 || CS.L = 1). CS.D value has no impact on address calculation.

Segment prefix override is ignored. Address size prefix (67H) override is ignored.

REX prefix is ignored in 64-bit mode.

Operation

```
IN_64BIT_MODE← 0;
IF TSX_ACTIVE
    Then GOTO TSX_ABORT_PROCESSING; FI;

IF ( CR0.PE= 0 or RFLAGS.VM = 1 or IN_SMM or CPUID.SGX_LEAF.0:EAX.SE1 = 0 )
    Then #UD; FI;

IF (CR0.TS = 1)
    Then #NM; FI;

IF (CPL != 3)
    Then #UD; FI;

IF (IA32_FEATURE_CONTROL.LOCK = 0 or IA32_FEATURE_CONTROL.SGX_ENABLE = 0)
    Then #GP(0); FI;

IF (EAX is invalid leaf number)
    Then #GP(0); FI;

IF (CR0.PG = 0 or CR0.NE = 0)
    Then #GP(0); FI;

IN_64BIT_MODE ← IA32_EFER.LMA AND CS.L ? 1 : 0;
```

```
(*Check not in 16-bit mode and DS is not a 16-bit segment*)
IF (IN_64BIT_MODE = 0 and ((CS.D = 0) or (DS.B = 0) )
    Then #GP(0); FI;

IF (CR_ENCLAVE_MODE = 1 and ((EAX = EENTER) or (EAX = ERESUME) ) )
    Then #GP(0); FI;

IF (CR_ENCLAVE_MODE = 0 and ((EAX = EGETKEY) or (EAX = EREPORT) or (EAX = EEXIT) or (EAX = EACCEPT) or
    (EAX = EACCEPTCOPY) or (EAX = EMODPE) ) )
    Then #GP(0); FI;

Jump to leaf specific flow
```

Flags Affected

	If CR0.NE= 0.
#NM	If CR0.TS = 1.

41.3 INTEL® SGX SYSTEM LEAF FUNCTION REFERENCE

Leaf functions available with the ENCLS instruction mnemonic are covered in this section. In general, each instruction leaf requires EAX to specify the leaf function index and/or additional implicit registers specifying leaf-specific input parameters. An instruction operand encoding table provides details of each implicit register usage and associated input/output semantics.

In many cases, an input parameter specifies an effective address associated with a memory object inside or outside the EPC, the memory addressing semantics of these memory objects are also summarized in a separate table.

EADD—Add a Page to an Uninitialized Enclave

Opcode/ Instruction	Op/En	64/32 bit Mode Support	CPUID Feature Flag	Description
EAX = 01H ENCLS[EADD]	IR	V/V	SGX1	This leaf function adds a page to an uninitialized enclave.

Instruction Operand Encoding

Op/En	EAX	RBX	RCX
IR	EADD (In)	Address of a PAGEINFO (In)	Address of the destination EPC page (In)

Description

This leaf function copies a source page from non-enclave memory into the EPC, associates the EPC page with an SECS page residing in the EPC, and stores the linear address and security attributes in EPCM. As part of the association, the enclave offset and the security attributes are measured and extended into the SECS.MRENCLAVE. This instruction can only be executed when current privilege level is 0.

RBX contains the effective address of a PAGEINFO structure while RCX contains the effective address of an EPC page. The table below provides additional information on the memory parameter of EADD leaf function.

EADD Memory Parameter Semantics

PAGEINFO	PAGEINFO.SECS	PAGEINFO.SRCPGE	PAGEINFO.SECINFO	EPCPAGE
Read access permitted by Non Enclave	Read/Write access permitted by Enclave	Read access permitted by Non Enclave	Read access permitted by Non Enclave	Write access permitted by Enclave

The instruction faults if any of the following:

EADD Faulting Conditions

The operands are not properly aligned.	Unsupported security attributes are set.
Refers to an invalid SECS.	Reference is made to an SECS that is locked by another thread.
The EPC page is locked by another thread.	RCX does not contain an effective address of an EPC page.
The EPC page is already valid.	If security attributes specifies a TCS and the source page specifies unsupported TCS values or fields.
The SECS has been initialized.	The specified enclave offset is outside of the enclave address space.

Concurrency Restrictions

EAUG—Add a Page to an Initialized Enclave

Opcode/ Instruction	Op/En	64/32 bit Mode Support	CPUID Feature Flag	Description
EAX = 0DH ENCLS[EAUG]	IR	V/V	SGX2	This leaf function adds a page to an initialized enclave.

Instruction Operand Encoding

Op/En	EAX	RBX	RCX
IR	EAUG (In)	Address of a SECINFO (In)	Address of the destination EPC page (In)

Description

This leaf function zeroes a page of EPC memory, associates the EPC page with an SECS page residing in the EPC, and stores the linear address and security attributes in the EPCM. As part of the association, the security attributes are configured to prevent access to the EPC page until a corresponding invocation of the EACCEPT leaf or EACCEPTCOPY leaf confirms the addition of the new page into the enclave. This instruction can only be executed when current privilege level is 0.

RBX contains the effective address of a PAGEINFO structure while RCX contains the effective address of an EPC page. The table below provides additional information on the memory parameter of the EAUG leaf function.

EAUG Memory Parameter Semantics

PAGEINFO	PAGEINFO.SECS	PAGEINFO.SRCPGE	PAGEINFO.SECINFO	EPCPAGE
Read access permitted by Non Enclave	Read/Write access permitted by Enclave	Must be zero	Read access permitted by Non Enclave	Write access permitted by Enclave

The instruction faults if any of the following:

EAUG Faulting Conditions

The operands are not properly aligned.	Unsupported security attributes are set.
Refers to an invalid SECS.	Reference is made to an SECS that is locked by another thread.
The EPC page is locked by another thread.	RCX does not contain an effective address of an EPC page.
The EPC page is already valid.	The specified enclave offset is outside of the enclave address space.
The SECS has been initialized.

Flags Affected

None

Protected Mode Exceptions

#GP(0)	If a memory operand effective address is outside the DS segment limit.
	If a memory operand is not properly aligned.
	If a memory operand is locked.
	If the enclave is not initialized.
#PF(fault code)	If a page fault occurs in accessing memory operands.

64-Bit Mode Exceptions

#GP(0)	If a memory operand is non-canonical form.
	If a memory operand is not properly aligned.
	If a memory operand is locked.
	If the enclave is not initialized.
#PF(fault code)	If a page fault occurs in accessing memory operands.

EBLOCK—Mark a page in EPC as Blocked

Opcode/ Instruction	Op/En	64/32 bit Mode Support	CPUID Feature Flag	Description
EAX = 09H ENCLS[EBLOCK]	IR	V/V	SGX1	This leaf function marks a page in the EPC as blocked.

Instruction Operand Encoding

Op/En	EAX		RCX
IR	EBLOCK (In)	Return error code (Out)	Effective address of the EPC page (In)

Description

This leaf function causes an EPC page to be marked as BLOCKED. This instruction can only be executed when current privilege level is 0.

The content of RCX is an effective address of an EPC page. The DS segment is used to create linear address. Segment override is not supported.

An error code is returned in RAX.

The table below provides additional information on the memory parameter of EBLOCK leaf function.

EBLOCK Memory Parameter Semantics

EPCPAGE
Read/Write access permitted by Enclave

The error codes are:

EBLOCK Error Codes

0 (No Error)	EBLOCK successful
SGX_BLKSTATE	Page already blocked. This value is used to indicate that the page was already EBLOCKed and thus will need to be restored to this state when it is eventually reloaded (using ELDB).
SGX_ENTRYEPOCH_LOCKED	This value indicates that an ETRACK is currently executing on the SECS. The EBLOCK should be re-attempted.
SGX_NOTBLOCKABLE	Page type is not one which can be blocked.
SGX_PG_INVLD	Page is not valid and cannot be blocked.
SGX_LOCKFAIL	Page is being written by ECREATE, ELDU/ELDB, or EWB.

	If a memory operand is not properly aligned.
	If the specified EPC resource is in use.
#PF(fault code)	If a page fault occurs in accessing memory operands.
	If a memory operand is not an EPC page.

ECREATE—Create an SECS page in the Enclave Page Cache

Opcode/ Instruction	Op/En	64/32 bit Mode Support	CPUID Feature Flag	Description
EAX = 00H ENCLS[ECREATE]	IR	V/V	SGX1	This leaf function begins an enclave build by creating an SECS page in EPC.

Instruction Operand Encoding

Op/En	EAX	RBX	RCX
IR	ECREATE (In)	Address of a PAGEINFO (In)	Address of the destination SECS page (In)

Description

ENCLS[ECREATE] is the first instruction executed in the enclave build process. ECREATE copies an SECS structure outside the EPC into an SECS page inside the EPC. The internal structure of SECS is not accessible to software.

ECREATE will set up fields in the protected SECS and mark the page as valid inside the EPC. ECREATE initializes or checks unused fields.

Software sets the following fields in the source structure: SECS:BASEADDR, SECS:SIZE in bytes, and ATTRIBUTES. SECS:BASEADDR must be naturally aligned on an SECS.SIZE boundary. SECS.SIZE must be at least 2 pages (8192).

The source operand RBX contains an effective address of a PAGEINFO structure. PAGEINFO contains an effective address of a source SECS and an effective address of an SECINFO. The SECS field in PAGEINFO is not used.

The RCX register is the effective address of the destination SECS. It is an address of an empty slot in the EPC. The SECS structure must be page aligned. SECINFO flags must specify the page as an SECS page.

ECREATE Memory Parameter Semantics

PAGEINFO	PAGEINFO.SRCPGE	PAGEINFO.SECINFO	EPCPAGE
Read access permitted by Non Enclave	Read access permitted by Non Enclave	Read access permitted by Non Enclave	Write access permitted by Enclave

ECREATE will fault if the SECS target page is in use; already valid; outside the EPC. It will also fault if addresses are not aligned; unused PAGEINFO fields are not zero.

If the amount of space needed to store the SSA frame is greater than the amount specified in SECS.SSAFRAME-SIZE, a #GP(0) results. The amount of space needed for an SSA frame is computed based on DS:TMP_SECS.ATTRIBUTES.XFRM size. Details of computing the size can be found Section 42.7.

EDBGRD—Read From a Debug Enclave

Opcode/ Instruction	Op/En	64/32 bit Mode Support	CPUID Feature Flag	Description
EAX = 04H ENCLS[EDBGRD]	IR	V/V	SGX1	This leaf function reads a dword/quadword from a debug enclave.

Instruction Operand Encoding

Op/En	EAX	RBX	RCX
IR	EDBGRD (In)	Data read from a debug enclave (Out)	Address of source memory in the EPC (In)

Description

This leaf function copies a quadword/doubleword from an EPC page belonging to a debug enclave into the RBX register. Eight bytes are read in 64-bit mode, four bytes are read in non-64-bit modes. The size of data read cannot be overridden.

The effective address of the source location inside the EPC is provided in the register RCX.

EDBGRD Memory Parameter Semantics

EPCQW
Read access permitted by Enclave

The instruction faults if any of the following:

EDBGRD Faulting Conditions

RCX points into a page that is an SECS.	RCX does not resolve to a naturally aligned linear address.
RCX points to a page that does not belong to an enclave that is in debug mode.	RCX points to a location inside a TCS that is beyond the architectural size of the TCS (SGX_TCS_LIMIT).
An operand causing any segment violation.	May page fault.
CPL != 0.	

This instruction ignores the EPCM RWX attributes on the enclave page. Consequently, violation of EPCM RWX attributes via EDGBRD does not result in a #GP.

EDBGWR—Write to a Debug Enclave

Opcode/ Instruction	Op/En	64/32 bit Mode Support	CPUID Feature Flag	Description
EAX = 05H ENCLS[EDBGWR]	IR	V/V	SGX1	This leaf function writes a dword/quadword to a debug enclave.

Instruction Operand Encoding

Op/En	EAX	RBX	RCX
IR	EDBGWR (In)	Data to be written to a debug enclave (In)	Address of Target memory in the EPC (In)

Description

This leaf function copies the content in EBX/RBX to an EPC page belonging to a debug enclave. Eight bytes are written in 64-bit mode, four bytes are written in non-64-bit modes. The size of data cannot be overridden.

The effective address of the source location inside the EPC is provided in the register RCX

EDBGWR Memory Parameter Semantics

EPCQW
Write access permitted by Enclave

The instruction faults if any of the following:

EDBGWR Faulting Conditions

RCX points into a page that is an SECS.	RCX does not resolve to a naturally aligned linear address.
RCX points to a page that does not belong to an enclave that is in debug mode.	RCX points to a location inside a TCS that is not the FLAGS word.
An operand causing any segment violation.	May page fault.
CPL != 0.	

This instruction ignores the EPCM RWX attributes on the enclave page. Consequently, violation of EPCM RWX attributes via EDGBRD does not result in a #GP.

EEXTEND—Extend Uninitialized Enclave Measurement by 256 Bytes

Opcode/ Instruction	Op/En	64/32 bit Mode Support	CPUID Feature Flag	Description
EAX = 06H ENCLS[EEXTEND]	IR	V/V	SGX1	This leaf function measures 256 bytes of an uninitialized enclave page.

Instruction Operand Encoding

Op/En	EAX	EBX	RCX
IR	EEXTEND (In)	Effective address of the SECS of the data chunk (In)	Effective address of a 256-byte chunk in the EPC (In)

Description

This leaf function updates the MRENCLAVE measurement register of an SECS with the measurement of an EXTEND string compromising of "EEXTEND" || ENCLAVEOFFSET || PADDING || 256 bytes of the enclave page. This instruction can only be executed when current privilege level is 0 and the enclave is uninitialized.

RBX contains the effective address of the SECS of the region to be measured. The address must be the same as the one used to add the page into the enclave.

RCX contains the effective address of the 256 byte region of an EPC page to be measured. The DS segment is used to create linear addresses. Segment override is not supported.

EEXTEND Memory Parameter Semantics

EPC[RCX]
Read access by Enclave

The instruction faults if any of the following:

EEXTEND Faulting Conditions

RBX points to an address not 4KBytes aligned.	RBX does not resolve to an SECS.
RBX does not point to an SECS page.	RBX does not point to the SECS page of the data chunk.
RCX points and address not 256B aligned.	RCX points to an unused page or a SECS.
RCX does not resolve in an EPC page.	If SECS is locked.
If the SECS is already initialized.	May page fault.
CPL != 0.

EINIT—Initialize an Enclave for Execution

Opcode/ Instruction	Op/En	64/32 bit Mode Support	CPUID Feature Flag	Description
EAX = 02H ENCLS[EINIT]	IR	V/V	SGX1	This leaf function initializes the enclave and makes it ready to execute enclave code.

Instruction Operand Encoding

Op/En	EAX		RBX	RCX	RDX
IR	EINIT (In)	Error code (Out)	Address of SIGSTRUCT (In)	Address of SECS (In)	Address of EINITTOKEN (In)

Description

This leaf function is the final instruction executed in the enclave build process. After EINIT, the MRENCLAVE measurement is complete, and the enclave is ready to start user code execution using the EENTER instruction.

EINIT takes the effective address of a SIGSTRUCT and EINITTOKEN. The SIGSTRUCT describes the enclave including MRENCLAVE, ATTRIBUTES, ISVSVN, a 3072 bit RSA key, and a signature using the included key. SIGSTRUCT must be populated with two values, q1 and q2. These are calculated using the formulas shown below:

q1 = floor(Signature^2 / Modulus);

q2 = floor((Signature^3 - q1 * Signature * Modulus) / Modulus);

The EINITTOKEN contains the MRENCLAVE, MRSIGNER, and ATTRIBUTES. These values must match the corresponding values in the SECS. If the EINITTOKEN was created with a debug launch key, the enclave must be in debug mode as well.

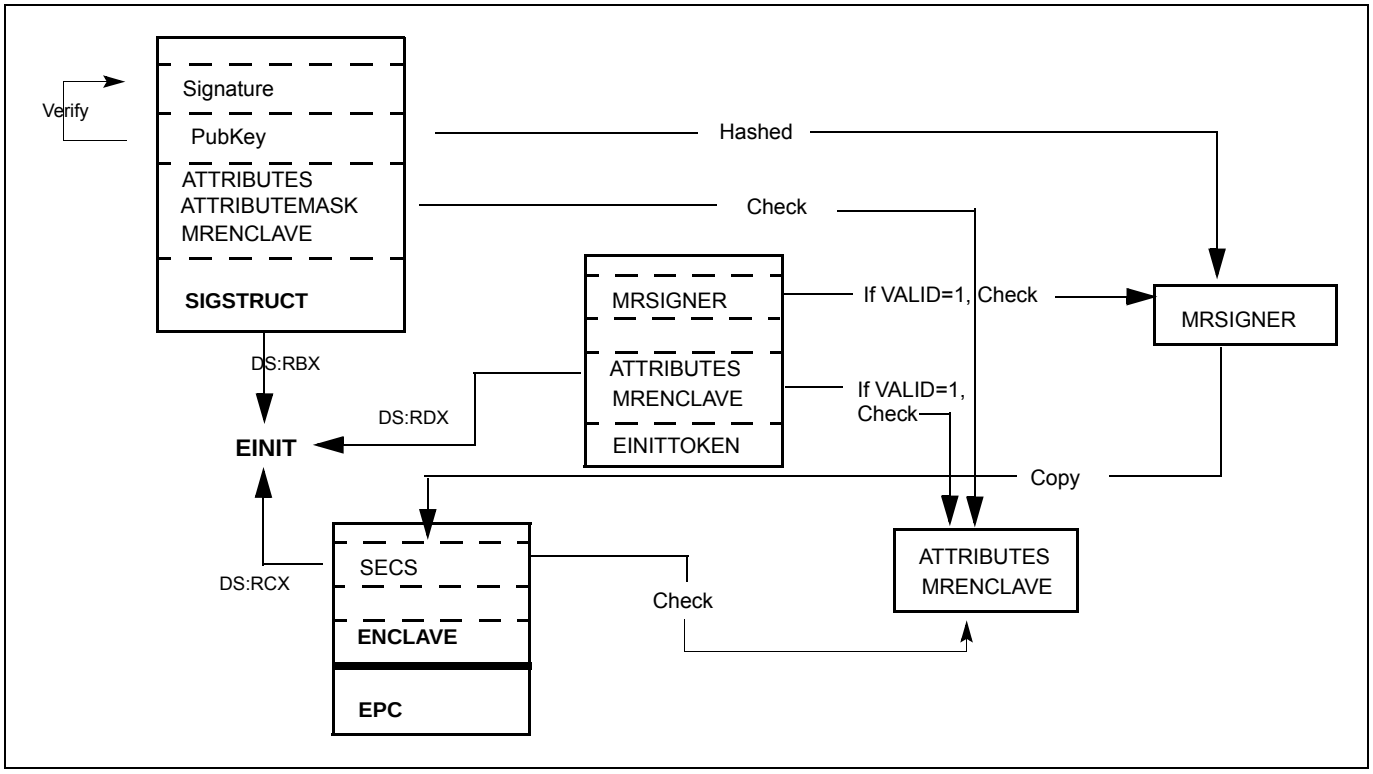

Figure 41-1. Relationships Between SECS, SIGSTRUCT and EINITTOKEN

EINIT Memory Parameter Semantics

SIGSTRUCT	SECS	EINITTOKEN
Access by non-Enclave	Read/Write access by Enclave	Access by non-Enclave

EINIT performs the following steps, which can be seen in Figure 41-1:

Validates that SIGSTRUCT is signed using the enclosed public key.

Checks that the completed computation of SECS.MRENCLAVE equals SIGSTRUCT.HASHENCLAVE.

Checks that no reserved bits are set to 1 in SIGSTRUCT.ATTRIBUTES and no reserved bits in SIGSTRUCT.ATTRIBUTESMASK are set to 0.

Checks that no Intel-only bits are set in SIGSTRUCT.ATTRIBUTES unless SIGSTRUCT was signed by Intel.

Checks that SIGSTRUCT.ATTRIBUTES equals the result of logically and-ing SIGSTRUCT.ATTRIBUTEMASK with SECS.ATTRIBUTES.

If EINITTOKEN.VALID is 0, checks that SIGSTRUCT is signed by Intel.

If EINITTOKEN.VALID is 1, checks the validity of EINITTOKEN.

If EINITTOKEN.VALID is 1, checks that EINITTOKEN.MRENCLAVE equals SECS.MRENCLAVE.

If EINITTOKEN.VALID is 1 and EINITTOKEN.ATTRIBUTES.DEBUG is 1, SECS.ATTRIBUTES.DEBUG must be 1.

Commits SECS.MRENCLAVE, and sets SECS.MRSIGNER, SECS.ISVSVN, and SECS.ISVPRODID based on SIGSTRUCT.

Update the SECS as Initialized.

Periodically, EINIT polls for certain asynchronous events. If such an event is detected, it completes with failure code (ZF=1 and RAX = SGX_UNMASKED_EVENT), and RIP is incremented to point to the next instruction. These events are INTR, NMI, SMI, INIT, VMX_TIMER, MCAKIND, MCE_SMI, and CMCI_SMI. EINIT does not fail if the pending event is inhibited (e.g., INTR could be inhibited due to MOV/POP SS blocking and STI blocking).

RFLAGS.{CF,PF,AF,OF,SF} are set to 0. When the instruction completes with an error, RFLAGS.ZF is set to 1, and the corresponding error bit is set in RAX. If no error occurs, RFLAGS.ZF is cleared and RAX is set to 0.

Flags Affected

ZF is cleared if successful, otherwise ZF is set and RAX contains the error code. CF, PF, AF, OF, SF are cleared.

Protected Mode Exceptions

#GP(0)	If a memory operand is not properly aligned.
	If another instruction is modifying the SECS.
	If the enclave is already initialized.
	If the SECS.MRENCLAVE is in use.
#PF(fault code)	If a page fault occurs in accessing memory operands.
	If RCX does not resolve in an EPC page.
	If the memory address is not a valid, uninitialized SECS.

64-Bit Mode Exceptions

#GP(0)	If a memory operand is not properly aligned. If another instruction is modifying the SECS. If the enclave is already initialized. If the SECS.MRENCLAVE is in use.
#PF(fault code)	If a page fault occurs in accessing memory operands. If RCX does not resolve in an EPC page. If the memory address is not a valid, uninitialized SECS.

ELDB/ELDU—Load an EPC page and Marked its State

Opcode/ Instruction	Op/En	64/32 bit Mode Support	CPUID Feature Flag	Description
EAX = 07H ENCLS[ELDB]	IR	V/V	SGX1	This leaf function loads, verifies an EPC page and marks the page as blocked.
EAX = 08H ENCLS[ELDU]	IR	V/V	SGX1	This leaf function loads, verifies an EPC page and marks the page as unblocked.

Instruction Operand Encoding

Op/En	EAX		RBX	RCX	RDX
IR	ELDB/ELDU (In)	Return error code (Out)	Address of the PAGEINFO (In)	Address of the EPC page (In)	Address of the version-array slot (In)

Description

This leaf function copies a page from regular main memory to the EPC. As part of the copying process, the page is cryptographically authenticated and decrypted. This instruction can only be executed when current privilege level is 0.

The ELDB leaf function sets the BLOCK bit in the EPCM entry for the destination page in the EPC after copying. The ELDU leaf function clears the BLOCK bit in the EPCM entry for the destination page in the EPC after copying.

RBX contains the effective address of a PAGEINFO structure; RCX contains the effective address of the destination EPC page; RDX holds the effective address of the version array slot that holds the version of the page.

The table below provides additional information on the memory parameter of ELDB/ELDU leaf functions.

EBLDB/ELDBU Memory Parameter Semantics

PAGEINFO	PAGEINFO.SRCPGE	PAGEINFO.PCMD	PAGEINFO.SECS	EPCPAGE	Version-Array Slot
Non-enclave read access	Non-enclave read access	Non-enclave read access	Enclave read/write access	Read/Write access permitted by Enclave	Read/Write access permitted by Enclave

The error codes are:

ELDB/ELDU Error Codes

0 (No Error)	ELDB/ELDU successful
SGX_MAC_COMPARE_FAIL	If the MAC check fails.

#GP(0)	If a memory operand is non-canonical form.

	If a memory operand is not properly aligned. If the instruction's EPC resource is in use by others. If the instruction fails to verify MAC. If the version-array slot is in use. If the parameters fail consistency checks.
#PF(fault code)	If a page fault occurs in accessing memory operands. If a memory operand expected to be in EPC does not resolve to an EPC page. If one of the EPC memory operands has incorrect page type. If the destination EPC page is already valid.

EMODPR—Restrict the Permissions of an EPC Page

Opcode/ Instruction	Op/En	64/32 bit Mode Support	CPUID Feature Flag	Description
EAX = 0EH ENCLS[EMODPR]	IR	V/V	SGX2	This leaf function restricts the access rights associated with a EPC page in an initialized enclave.

Instruction Operand Encoding

Op/En	EAX		RBX	RCX
IR	EMODPR (In)	Return Error Code (Out)	Address of a SECINFO (In)	Address of the destination EPC page (In)

Description

This leaf function restricts the access rights associated with an EPC page in an initialized enclave. THE RWX bits of the SECINFO parameter are treated as a permissions mask; supplying a value that does not restrict the page permissions will have no effect. This instruction can only be executed when current privilege level is 0.

RBX contains the effective address of a SECINFO structure while RCX contains the effective address of an EPC page. The table below provides additional information on the memory parameter of the EMODPR leaf function.

EMODPR Memory Parameter Semantics

SECINFO	EPCPAGE
Read access permitted by Non Enclave	Read/Write access permitted by Enclave

The instruction faults if any of the following:

EMODPR Faulting Conditions

The operands are not properly aligned.	If unsupported security attributes are set.
The Enclave is not initialized.	SECS is locked by another thread.
The EPC page is locked by another thread.	RCX does not contain an effective address of an EPC page in the running enclave.
The EPC page is not valid.

EMODT—Change the Type of an EPC Page

Opcode/ Instruction	Op/En	64/32 bit Mode Support	CPUID Feature Flag	Description
EAX = 0FH ENCLS[EMODT]	IR	V/V	SGX2	This leaf function changes the type of an existing EPC page.

Instruction Operand Encoding

Op/En	EAX		RBX	RCX
IR	EMODT (In)	Return Error Code (Out)	Address of a SECINFO (In)	Address of the destination EPC page (In)

Description

This leaf function modifies the type of an EPC page. The security attributes are configured to prevent access to the EPC page at its new type until a corresponding invocation of the EACCEPT leaf confirms the modification. This instruction can only be executed when current privilege level is 0.

RBX contains the effective address of a SECINFO structure while RCX contains the effective address of an EPC page. The table below provides additional information on the memory parameter of the EMODT leaf function.

EMODT Memory Parameter Semantics

SECINFO	EPCPAGE
Read access permitted by Non Enclave	Read/Write access permitted by Enclave

The instruction faults if any of the following:

EMODT Faulting Conditions

The operands are not properly aligned.	If unsupported security attributes are set.
The Enclave is not initialized.	SECS is locked by another thread.
The EPC page is locked by another thread.	RCX does not contain an effective address of an EPC page in the running enclave.
The EPC page is not valid.

EPA—Add Version Array

Opcode/ Instruction	Op/En	64/32 bit Mode Support	CPUID Feature Flag	Description
EAX = 0AH ENCLS[EPA]	IR	V/V	SGX1	This leaf function adds a Version Array to the EPC.

Instruction Operand Encoding

Op/En	EAX	RBX	RCX
IR	EPA (In)	PT_VA (In, Constant)	Effective address of the EPC page (In)

Description

This leaf function creates an empty version array in the EPC page whose logical address is given by DS:RCX, and sets up EPCM attributes for that page. At the time of execution of this instruction, the register RBX must be set to PT_VA.

The table below provides additional information on the memory parameter of EPA leaf function.

EPA Memory Parameter Semantics

EPCPAGE
Write access permitted by Enclave

Flags Affected

None

Protected Mode Exceptions

#GP(0)	If a memory operand effective address is outside the DS segment limit.
	If a memory operand is not properly aligned.
	If another Intel SGX instruction is accessing the EPC page.
	If RBX is not set to PT_VA.
#PF(fault code)	If a page fault occurs in accessing memory operands.
	If a memory operand is not an EPC page.
	If the EPC page is valid.

64-Bit Mode Exceptions

#GP(0)	If a memory operand is non-canonical form.
	If a memory operand is not properly aligned.
	If another Intel SGX instruction is accessing the EPC page.
	If RBX is not set to PT_VA.
#PF(fault code)	If a page fault occurs in accessing memory operands.
	If a memory operand is not an EPC page.
	If the EPC page is valid.

EREMOVE—Remove a page from the EPC

Opcode/ Instruction	Op/En	64/32 bit Mode Support	CPUID Feature Flag	Description
EAX = 03H ENCLS[EREMOVE]	IR	V/V	SGX1	This leaf function removes a page from the EPC.

Instruction Operand Encoding

Op/En	EAX	RCX
IR	EREMOVE (In)	Effective address of the EPC page (In)

Description

This leaf function causes an EPC page to be un-associated with its SECS and be marked as unused. This instruction leaf can only be executed when the current privilege level is 0.

The content of RCX is an effective address of an EPC page. The DS segment is used to create linear address. Segment override is not supported.

The instruction fails if the operand is not properly aligned or does not refer to an EPC page or the page is in use by another thread, or other threads are running in the enclave to which the page belongs. In addition the instruction fails if the operand refers to an SECS with associations.

EREMOVE Memory Parameter Semantics

EPCPAGE
Write access permitted by Enclave

The instruction faults if any of the following:

EREMOVE Faulting Conditions

The memory operand is not properly aligned.	The memory operand does not resolve in an EPC page.
Refers to an invalid SECS.	Refers to an EPC page that is locked by another thread.
Another Intel SGX instruction is accessing the EPC page.	RCX does not contain an effective address of an EPC page.
the EPC page refers to an SECS with associations.	

The error codes are:

EREMOVE Error Codes

0 (No Error)	EREMOVE successful.
SGX_CHILD_PRESENT	If the SECS still have enclave pages loaded into EPC.
SGX_ENCLAVE_ACT	If there are still logical processors executing inside the enclave.

	If a memory operand is not an EPC page.
	If one of the EPC memory operands has incorrect page type.

41.4 INTEL® SGX USER LEAF FUNCTION REFERENCE

41.4.1 Instruction Column in the Instruction Summary Table

Leaf functions available with the ENCLU instruction mnemonic are covered in this section. In general, each instruction leaf requires EAX to specify the leaf function index and/or additional registers specifying leaf-specific input parameters. An instruction operand encoding table provides details of the implicitly-encoded register usage and associated input/output semantics.

In many cases, an input parameter specifies an effective address associated with a memory object inside or outside the EPC, the memory addressing semantics of these memory objects are also summarized in a separate table.

EACCEPT—Accept Changes to an EPC Page

Opcode/ Instruction	Op/En	64/32 bit Mode Support	CPUID Feature Flag	Description
EAX = 05H ENCLU[EACCEPT]	IR	V/V	SGX2	This leaf function accepts changes made by system software to an EPC page in the running enclave.

Instruction Operand Encoding

Op/En	EAX		RBX	RCX
IR	EACCEPT (In)	Return Error Code (Out)	Address of a SECINFO (In)	Address of the destination EPC page (In)

Description

This leaf function accepts changes to a page in the running enclave by verifying that the security attributes specified in the SECINFO match the security attributes of the page in the EPCM. This instruction leaf can only be executed when inside the enclave.

RBX contains the effective address of a SECINFO structure while RCX contains the effective address of an EPC page. The table below provides additional information on the memory parameter of the EACCEPT leaf function.

EACCEPT Memory Parameter Semantics

SECINFO	EPCPAGE (Destination)
Read access permitted by Non Enclave	Read access permitted by Enclave

The instruction faults if any of the following:

EACCEPT Faulting Conditions

The operands are not properly aligned.	If security attributes of the SECINFO page make the page inaccessible.
The EPC page is locked by another thread.	RBX does not contain an effective address in an EPC page in the running enclave.
The EPC page is not valid.	RCX does not contain an effective address of an EPC page in the running enclave.
SECINFO contains an invalid request.	Page type is PT_REG and MODIFIED bit is 0.
	Page type is PT_TCS or PT_TRIM and PENDING bit is 0 and MODIFIED bit is 1.

	If a memory operand is not properly aligned.
	If a memory operand is locked.
#PF(fault code)	If a page fault occurs in accessing memory operands.
	If a memory operand is not an EPC page.
	If EPC page has incorrect page type or security attributes.

EACCEPTCOPY—Initialize a Pending Page

Opcode/ Instruction	Op/En	64/32 bit Mode Support	CPUID Feature Flag	Description
EAX = 07H ENCLU[EACCEPTCOPY]	IR	V/V	SGX2	This leaf function initializes a dynamically allocated EPC page from another page in the EPC.

Instruction Operand Encoding

Op/En	EAX		RBX	RCX	RDX
IR	EACCEPTCOPY (In)	Return Error Code (Out)	Address of a SECINFO (In)	Address of the destination EPC page (In)	Address of the source EPC page (In)

Description

This leaf function copies the contents of an existing EPC page into an uninitialized EPC page (created by EAUG). After initialization, the instruction may also modify the access rights associated with the destination EPC page. This instruction leaf can only be executed when inside the enclave.

RBX contains the effective address of a SECINFO structure while RCX and RDX each contain the effective address of an EPC page. The table below provides additional information on the memory parameter of the EACCEPTCOPY leaf function.

EACCEPTCOPY Memory Parameter Semantics

SECINFO	EPCPAGE (Destination)	EPCPAGE (Source)
Read access permitted by Non Enclave	Read/Write access permitted by Enclave	Read access permitted by Enclave

The instruction faults if any of the following:

EACCEPTCOPY Faulting Conditions

The operands are not properly aligned.	If security attributes of the SECINFO page make the page inaccessible.
The EPC page is locked by another thread.	If security attributes of the source EPC page make the page inaccessible.
The EPC page is not valid.	RBX does not contain an effective address in an EPC page in the running enclave.
SECINFO contains an invalid request.	RCX/RDX does not contain an effective address of an EPC page in the running enclave.

EENTER—Enters an Enclave

Opcode/ Instruction	Op/En	64/32 bit Mode Support	CPUID Feature Flag	Description
EAX = 02H ENCLU[EENTER]	IR	V/V	SGX1	This leaf function is used to enter an enclave.

Instruction Operand Encoding

Op/En	EAX		RBX	RCX	
IR	EENTER (In)	Content of RBX.CSSA (Out)	Address of a TCS (In)	Address of AEP (In)	Address of IP following EENTER (Out)

Description

The ENCLU[EENTER] instruction transfers execution to an enclave. At the end of the instruction, the logical processor is executing in enclave mode at the RIP computed as EnclaveBase + TCS.OENTRY. If the target address is not within the CS segment (32-bit) or is not canonical (64-bit), a #GP(0) results.

EENTER Memory Parameter Semantics

TCS
Enclave access

EENTER is a serializing instruction. The instruction faults if any of the following occurs:

Address in RBX is not properly aligned.	Any TCS.FLAGS's must-be-zero bit is not zero.
TCS pointed to by RBX is not valid or available or locked.	Current 32/64 mode does not match the enclave mode in SECS.ATTRIBUTES.MODE64.
The SECS is in use.	Either of TCS-specified FS and GS segment is not a subsets of the current DS segment.
Any one of DS, ES, CS, SS is not zero.	If XSAVE available, CR4.OSXSAVE = 0, but SECS.ATTRIBUTES.XFRM != 0x3.
CR4.OSFXSR != 1.	If CR4.OSXSAVE = 1, SECS.ATTRIBUTES.XFRM is not a subset of XCR0.

The following operations are performed by EENTER:

- RSP and RBP are saved in the current SSA frame on EENTER and are automatically restored on EEXIT or interrupt.
- The AEP contained in RCX is stored into the TCS for use by AEXs.FS and GS (including hidden portions) are saved and new values are constructed using TCS.OFSBASE/GSBASE (32 and 64-bit mode) and TCS.OFSLIMIT/GSLIMIT (32-bit mode only). The resulting segments must be a subset of the DS segment.
- If CR4.OSXSAVE == 1, XCR0 is saved and replaced by SECS.ATTRIBUTES.XFRM.The effect of RFLAGS.TF depends on whether the enclave entry is opt-in or opt-out (see Section 43.1.2):
  - — On opt-out entry, TF is saved and cleared (it is restored on EEXIT or AEX). Any attempt to set TF via a POPF instruction while inside the enclave clears TF (see Section 43.2.5).
  - — On opt-in entry, a single-step debug exception is pended on the instruction boundary immediately after EENTER (see Section 43.2.2).
- All code breakpoints that do not overlap with ELRANGE are also suppressed. If the entry is an opt-out entry, all code and data breakpoints that overlap with the ELRANGE are suppressed.
- On opt-out entry, a number of performance monitoring counters and behaviors are modified or suppressed (see Section 43.2.3):

— All performance monitoring activity on the current thread is suppressed except for incrementing and firing of FIXED_CTR1 and FIXED_CTR2.

— PEBS is suppressed.

— AnyThread counting on other threads is demoted to MyThread mode and IA32_PERF_GLOBAL_STATUS[60] on that thread is set

— If the opt-out entry on a hardware thread results in suppression of any performance monitoring, then the processor sets IA32_PERF_GLOBAL_STATUS[60] and IA32_PERF_GLOBAL_STATUS[63].

Protected Mode Exceptions

#GP(0)	If DS:RBX is not page aligned.
	If the enclave is not initialized.
	If part or all of the FS or GS segment specified by TCS is outside the DS segment or not properly aligned.
	If the thread is not in the INACTIVE state.
	If CS, DS, ES or SS bases are not all zero.
	If executed in enclave mode.
	If any reserved field in the TCS FLAG is set.
	If the target address is not within the CS segment.
	If CR4.OSFXSR = 0.
	If CR4.OSXSAVE = 0 and SECS.ATTRIBUTES.XFRM != 3.
	If CR4.OSXSAVE = 1and SECS.ATTRIBUTES.XFRM is not a subset of XCR0.
#PF(fault code)	If a page fault occurs in accessing memory.
	If DS:RBX does not point to a valid TCS.
	If one or more pages of the current SSA frame are not readable/writable, or do not resolve to a valid PT_REG EPC page.
#NM	If CR0.TS is set.

64-Bit Mode Exceptions

#GP(0)	If DS:RBX is not page aligned.
	If the enclave is not initialized.
	If the thread is not in the INACTIVE state.

	If CS, DS, ES or SS bases are not all zero.
	If executed in enclave mode.
	If part or all of the FS or GS segment specified by TCS is outside the DS segment or not properly aligned.
	If the target address is not canonical.
	If CR4.OSFXSR = 0.
	If CR4.OSXSAVE = 0 and SECS.ATTRIBUTES.XFRM != 3.
	If CR4.OSXSAVE = 1and SECS.ATTRIBUTES.XFRM is not a subset of XCR0.
#PF(fault code)	If a page fault occurs in accessing memory operands.
	If DS:RBX does not point to a valid TCS.
	If one or more pages of the current SSA frame are not readable/writable, or do not resolve to a valid PT_REG EPC page.
#NM	If CR0.TS is set.

EEXIT—Exits an Enclave

Opcode/ Instruction	Op/En	64/32 bit Mode Support	CPUID Feature Flag	Description
EAX = 04H ENCLU[EEXIT]	IR	V/V	SGX1	This leaf function is used to exit an enclave.

Instruction Operand Encoding

Op/En	EAX	RBX	RCX
IR	EEXIT (In)	Target address outside the enclave (In)	Address of the current AEP (In)

Description

The ENCLU[EEXIT] instruction exits the currently executing enclave and branches to the location specified in RBX. RCX receives the current AEP. If RBX is not within the CS (32-bit mode) or is not canonical (64-bit mode) a #GP(0) results.

EEXIT Memory Parameter Semantics

Target Address
non-Enclave read and execute access

If RBX specifies an address that is inside the enclave, the instruction will complete normally. The fetch of the next instruction will occur in non-enclave mode, but will attempt to fetch from inside the enclave. This has the effect of abort page semantics on the next destination.

If secrets are contained in any registers, it is responsibility of enclave software to clear those registers.

If XCR0 was modified on enclave entry, it is restored to the value it had at the time of the most recent EENTER or ERESUME.

If the enclave is opt-out, RFLAGS.TF is loaded from the value previously saved on EENTER.

Code and data breakpoints are unsuppressed.

Performance monitoring counters are unsuppressed.

EGETKEY—Retrieves a Cryptographic Key

Opcode/ Instruction	Op/En	64/32 bit Mode Support	CPUID Feature Flag	Description
EAX = 04H ENCLU[EGETKEY]	IR	V/V	SGX1	This leaf function retrieves a cryptographic key.

Instruction Operand Encoding

Op/En	EAX	RBX	RCX
IR	EGETKEY (In)	Address to a KEYREQUEST (In)	Address of the OUTPUTDATA (In)

Description

The ENCLU[EGETKEY] instruction returns a 128-bit secret key from the processor specific key hierarchy. The register RBX contains the effective address of a KEYREQUEST structure, which the instruction interprets to determine the key being requested. The Requesting Keys section below provides a description of the keys that can be requested. The RCX register contains the effective address where the key will be returned. Both the addresses in RBX & RCX should be locations inside the enclave.

EGETKEY derives keys using a processor unique value to create a specific key based on a number of possible inputs. This instruction leaf can only be executed inside an enclave.

EEGETKEY Memory Parameter Semantics

KEYREQUEST	OUTPUTDATA
Enclave read access	Enclave write access

After validating the operands, the instruction determines which key is to be produced and performs the following actions:

- The instruction assembles the derivation data for the key based on the Table 41-43
- Computes derived key using the derivation data and package specific value
- Outputs the calculated key to the address in RCX

The instruction fails with #GP(0) if the operands are not properly aligned. Successful completion of the instruction will clear RFLAGS.{ZF, CF, AF, OF, SF, PF}. The instruction returns an error code if the user tries to request a key based on an invalid CPUSVN or ISVSVN (when the user request is accepted, see the table below), requests a key for which it has not been granted the attribute to request, or requests a key that is not supported by the hardware. These checks may be performed in any order. Thus, an indication by error number of one cause (for example, invalid attribute) does not imply that there are not also other errors. Different processors may thus give different error numbers for the same Enclave. The correctness of software should not rely on the order resulting from the checks documented in this section. In such cases the ZF flag is set and the corresponding error bit (SGX_INVALID_SVN, SGX_INVALID_ATTRIBUTE, SGX_INVALID_KEYNAME) is set in RAX and the data at the address specified by RCX is unmodified.

Requesting Keys

The KEYREQUEST structure (see Section 38.17.1) identifies the key to be provided. The Keyrequest.KeyName field identifies which type of key is requested.

Deriving Keys

Key derivation is based on a combination of the enclave specific values (see Table 41-43) and a processor key. Depending on the key being requested a field may either be included by definition or the value may be included from the KeyRequest. A “yes” in Table 41-43 indicates the value for the field is included from its default location, identified in the source row, and a “request” indicates the values for the field is included from its corresponding KeyRequest field.

Table 41-43. Key Derivation

	Key Name	Attributes	Owner Epoch	CPU SVN	ISV SVN	ISV PRODID	MRENCLAVE	MRSIGNER	RAND
Source	Key Dependent Constant	Y← SECS.ATTRIBUTES and SECS.MISCSELECT;	CSR_SEOWNEREPOCH	Y← CPUSVN Register;	R← Req.ISVSVN;	SECS.ISVID	SECS.MRENCLAVE	SECS.MRSIGNER	Req.KEYID
		R←AttribMask & SECS.ATTRIBUTES and SECS.MISCSELECT;		R← Req.CPUSVN;					
Launch	Yes	Request	Yes	Request	Request	Yes	No	No	Request
Report	Yes	Yes	Yes	Yes	No	No	Yes	No	Request
Seal	Yes	Request	Yes	Request	Request	Yes	Request	Request	Request
Provisioning	Yes	Request	No	Request	Request	Yes	No	Yes	Yes
Provisioning Seal	Yes	Request	Yes	Request	Request	Yes	No	Yes	Yes

Keys that permit the specification of a CPU or ISV's code's SVNs have additional requirements. The caller may not request a key for an SVN beyond the current CPU or ISV SVN, respectively.

Some keys are derived based on a hardcode PKCS padding constant (352 byte string):

HARDCODED_PKCS1_5_PADDING[15:0] ß 0100H;

HARDCODED_PKCS1_5_PADDING[2655:16] ß SignExtend330Byte(-1); // 330 bytes of 0FFH

HARDCODED_PKCS1_5_PADDING[2815:2656] ß 2004000501020403650148866009060D30313000H;

The error codes are:

EGETKEY Error Codes

0 (No Error)	EGETKEY successful.
SGX_INVALID_ATTRIBUTE	The KEYREQUEST contains a KEYNAME for which the enclave is not authorized.
SGX_INVALID_CPUSVN	If KEYREQUEST.CPUSVN is beyond platforms CPUSVN value.
SGX_INVALID_ISVSVN	If KEYREQUEST.ISVSVN is greater than the enclave's ISV_SVN.
SGX_INVALID_KEYNAME	If KEYREQUEST.KEYNAME is an unsupported value.

Flags Affected

ZF is cleared if successful, otherwise ZF is set. CF, PF, AF, OF, SF are cleared.

Protected Mode Exceptions

#GP(0)	If a memory operand effective address is outside the current enclave.
	If an effective address is not properly aligned.
	If an effective address is outside the DS segment limit.
	If KEYREQUEST format is invalid.
#PF(fault code)	If a page fault occurs in accessing memory.

64-Bit Mode Exceptions

#GP(0)	If a memory operand effective address is outside the current enclave.
	If an effective address is not properly aligned.
	If an effective address is not canonical.
	If KEYREQUEST format is invalid.
#PF(fault code)	If a page fault occurs in accessing memory operands.

EMODPE—Extend an EPC Page Permissions

Opcode/ Instruction	Op/En	64/32 bit Mode Support	CPUID Feature Flag	Description
EAX = 06H ENCLU[EMODPE]	IR	V/V	SGX2	This leaf function extends the access rights of an existing EPC page.

Instruction Operand Encoding

Op/En	EAX	RBX	RCX
IR	EMODPE (In)	Address of a SECINFO (In)	Address of the destination EPC page (In)

Description

This leaf function extends the access rights associated with an existing EPC page in the running enclave. THE RWX bits of the SECINFO parameter are treated as a permissions mask; supplying a value that does not extend the page permissions will have no effect. This instruction leaf can only be executed when inside the enclave.

RBX contains the effective address of a SECINFO structure while RCX contains the effective address of an EPC page. The table below provides additional information on the memory parameter of the EMODPE leaf function.

EMODPE Memory Parameter Semantics

SECINFO	EPCPAGE
Read access permitted by Non Enclave	Read access permitted by Enclave

The instruction faults if any of the following:

EMODPE Faulting Conditions

The operands are not properly aligned.	If security attributes of the SECINFO page make the page inaccessible.
The EPC page is locked by another thread.	RBX does not contain an effective address in an EPC page in the running enclave.
The EPC page is not valid.	RCX does not contain an effective address of an EPC page in the running enclave.
SECINFO contains an invalid request.

EREPORT—Create a Cryptographic Report of the Enclave

Opcode/ Instruction	Op/En	64/32 bit Mode Support	CPUID Feature Flag	Description
EAX = 00H ENCLU[EREPORT]	IR	V/V	SGX1	This leaf function creates a cryptographic report of the enclave.

Instruction Operand Encoding

Op/En	EAX	RBX	RCX	RDX
IR	EREPORT (In)	Address of TARGETINFO (In)	Address of REPORTDATA (In)	Address where the REPORT is written to in an OUTPUTDATA (In)

Description

This leaf function creates a cryptographic REPORT that describes the contents of the enclave. This instruction leaf can only be executed when inside the enclave. The cryptographic report can be used by other enclaves to determine that the enclave is running on the same platform.

RBX contains the effective address of the MRENCLAVE value of the enclave that will authenticate the REPORT output, using the REPORT key delivered by EGETKEY command for that enclave. RCX contains the effective address of a 64-byte REPORTDATA structure, which allows the caller of the instruction to associate data with the enclave from which the instruction is called. RDX contains the address where the REPORT will be output by the instruction.

EREPORT Memory Parameter Semantics

TARGETINFO	REPORTDATA	OUTPUTDATA
Read access by Enclave	Read access by Enclave	Read/Write access by Enclave

This instruction leaf perform the following:

1. Validate the 3 operands (RBX, RCX, RDX) are inside the enclave.
2. Compute a report key for the target enclave, as indicated by the value located in RBX(TARGETINFO).
3. Assemble the enclave SECS data to complete the REPORT structure (including the data provided using the RCX (REPORTDATA) operand).
4. Computes a crytpographic hash over REPORT structure.
5. Add the computed hash to the REPORT structure.
6. Output the completed REPORT structure to the address in RDX (OUTPUTDATA).

The instruction fails if the operands are not properly aligned.

CR_REPORT_KEYID, used to provide key wearout protection, is populated with a statistically unique value on boot of the platform by a trusted entity within the SGX TCB.

The instruction faults if any of the following:

EREPORT Faulting Conditions

An effective address not properly aligned.	an memory address does not resolve in an EPC page.
If accessing an invalid EPC page.	If the EPC page is blocked.
May page fault.

ERESUME—Re-Enters an Enclave

Opcode/ Instruction	Op/En	64/32 bit Mode Support	CPUID Feature Flag	Description
EAX = 03H ENCLU[ERESUME]	IR	V/V	SGX1	This leaf function is used to re-enter an enclave after an interrupt.

Instruction Operand Encoding

Op/En	RAX	RBX	RCX
IR	ERESUME (In)	Address of a TCS (In)	Address of AEP (In)

Description

The ENCLU[ERESUME] instruction resumes execution of an enclave that was interrupted due to an exception or interrupt, using the machine state previously stored in the SSA.

ERESUME Memory Parameter Semantics

TCS
Enclave read/write access

The instruction faults if any of the following:

Address in RBX is not properly aligned.	Any TCS.FLAGS's must-be-zero bit is not zero.
TCS pointed to by RBX is not valid or available or locked.	Current 32/64 mode does not match the enclave mode in SECS.ATTRIBUTES.MODE64.
The SECS is in use by another enclave.	Either of TCS-specified FS and GS segment is not a subset of the current DS segment.
Any one of DS, ES, CS, SS is not zero.	If XSAVE available, CR4.OSXSAVE = 0, but SECS.ATTRIBUTES.XFRM != 0x3.
CR4.OSFXSR != 1.	If CR4.OSXSAVE = 1, SECS.ATTRIBUTES.XFRM is not a subset of XCR0.
Offsets 520-535 of the XSAVE area not 0.	The bit vector stored at offset 512 of the XSAVE area must be a subset of SECS.ATTRIBUTES.XFRM.
The SSA frame is not valid or in use.	

If CR0.TS is set, ERESUME generates a #NM exception.

The following operations are performed by ERESUME:

- RSP and RBP are saved in the current SSA frame on EENTER and are automatically restored on EEXIT or an asynchronous exit due to any Interrupt event.
- The AEP contained in RCX is stored into the TCS for use by AEXs.FS and GS (including hidden portions) are saved and new values are constructed using TCS.OFSBASE/GSBASE (32 and 64-bit mode) and TCS.OFSLIMIT/GSLIMIT (32-bit mode only). The resulting segments must be a subset of the DS segment.
- If CR4.OSXSAVE == 1, XCR0 is saved and replaced by SECS.ATTRIBUTES.XFRM.The effect of RFLAGS.TF depends on whether the enclave entry is opt-in or opt-out (see Section 43.1.2):
  - On opt-out entry, TF is saved and cleared (it is restored on EEXIT or AEX). Any attempt to set TF via a POPF instruction while inside the enclave clears TF (see Section 43.2.5).
  - On opt-in entry, a single-step debug exception is pended on the instruction boundary immediately after EENTER (see Section 43.2.3).
- All code breakpoints that do not overlap with ELRANGE are also suppressed. If the entry is an opt-out entry, all code and data breakpoints that overlap with the ELRANGE are suppressed.

- On opt-out entry, a number of performance monitoring counters and behaviors are modified or suppressed (see Section 43.2.3):
  - — All performance monitoring activity on the current thread is suppressed except for incrementing and firing of FIXED_CTR1 and FIXED_CTR2.
  - — PEBS is suppressed.
  - — AnyThread counting on other threads is demoted to MyThread mode and IA32_PERF_GLOBAL_STATUS[60] on that thread is set.
  - — If the opt-out entry on a hardware thread results in suppression of any performance monitoring, then the processor sets IA32_PERF_GLOBAL_STATUS[60] and IA32_PERF_GLOBAL_STATUS[63].

Flags Affected

RFLAGS.TF is cleared on opt-out entry

Protected Mode Exceptions

#GP(0)	If DS:RBX is not page aligned.
	If the enclave is not initialized.
	If the thread is not in the INACTIVE state.
	If CS, DS, ES or SS bases are not all zero.
	If executed in enclave mode.
	If part or all of the FS or GS segment specified by TCS is outside the DS segment.
	If any reserved field in the TCS FLAG is set.
	If the target address is not within the CS segment.
	If CR4.OSFXSR = 0.
	If CR4.OSXSAVE = 0 and SECS.ATTRIBUTES.XFRM != 3.
	If CR4.OSXSAVE = 1and SECS.ATTRIBUTES.XFRM is not a subset of XCR0.
#PF(fault code)	If a page fault occurs in accessing memory.
	If DS:RBX does not point to a valid TCS.
	If one or more pages of the current SSA frame are not readable/writable, or do not resolve to a valid PT_REG EPC page.
#NM	If CR0.TS is set.

64-Bit Mode Exceptions

#GP(0)	If DS:RBX is not page aligned.
	If the enclave is not initialized.
	If the thread is not in the INACTIVE state.
	If CS, DS, ES or SS bases are not all zero.
	If executed in enclave mode.
	If part or all of the FS or GS segment specified by TCS is outside the DS segment.
	If any reserved field in the TCS FLAG is set.
	If the target address is not canonical.
	If CR4.OSFXSR = 0.
	If CR4.OSXSAVE = 0 and SECS.ATTRIBUTES.XFRM != 3.
	If CR4.OSXSAVE = 1and SECS.ATTRIBUTES.XFRM is not a subset of XCR0.
#PF(fault code)	If a page fault occurs in accessing memory operands.
	If DS:RBX does not point to a valid TCS.
	If one or more pages of the current SSA frame are not readable/writable, or do not resolve to a valid PT_REG EPC page.
#NM	If CR0.TS is set.

CHAPTER 42
INTEL® SGX INTERACTIONS WITH IA32 AND INTEL® 64 ARCHITECTURE

Intel® SGX provides Intel® Architecture with a collection of enclave instructions for creating protected execution environments on processors supporting IA32 and Intel® 64 architectures. These Intel SGX instructions are designed to work with legacy software and the various IA32 and Intel 64 modes of operation.

42.1 INTEL® SGX AVAILABILITY IN VARIOUS PROCESSOR MODES

The Intel SGX extensions (see Table 37-1) are available only when the processor is executing in protected mode of operation. Additionally, the extensions are not available in System Management Mode (SMM) of operation or in Virtual 8086 (VM86) mode of operation. Finally, all leaf functions of ENCLU and ENCLS require CR0.PG enabled.

The exact details of exceptions resulting from illegal modes and their priority are listed in the reference pages of ENCLS and ENCLU.

42.2 IA32_FEATURE_CONTROL

A new bit in IA32_FEATURE_CONTROL MSR (bit 18) is provided to BIOS to control the availability of Intel SGX extensions. For Intel SGX extensions to be available on a logical processor, bit 18 in the IA32_FEATURE_CONTROL MSR on that logical processor must be set, and IA32_FEATURE_CONTROL MSR on that logical processor must be locked (bit 0 must be set). See Section 37.7.1 for additional details. OS is expected to examine the value of bit 18 prior to enabling Intel SGX on the thread, as the settings of bit 18 is not reflected by CPUID.

42.3 INTERACTIONS WITH SEGMENTATION

42.3.1 Scope of Interaction

Intel SGX extensions are available only when the processor is executing in a protected mode operation (see Section 42.1 for Intel SGX availability in various processor modes). Enclaves abide by all the segmentation policies set up by the OS, but they can be more restrictive than the OS.

Intel SGX interacts with segmentation at two levels:

- The Intel SGX instruction (see the enclave instruction in Table 37-1).
- While executing inside an enclave (legacy instructions and enclave instructions permitted inside an enclave).

42.3.2 Interactions of Intel® SGX Instructions with Segment, Operand, and Addressing Prefixes

All the memory operands used by the Intel SGX instructions are interpreted as offsets within the data segment (DS). The segment-override prefix on Intel SGX instructions is ignored.

Operand size is fixed for each enclave instruction. The operand-size prefix is reserved, and results in a #UD exception if used.

All address sizes are determined by the operating mode of the processor. The address-size prefix is ignored. This implies that while operating in 64-bit mode of operation, the address size is always 64 bits, and while operating in 32-bit mode of operation, the address size is always 32 bits. Additionally, when operating in 16-bit addressing, memory operands used by enclave instructions use 32 bit addressing; the value of CS.D is ignored.

42.3.3 Interaction of Intel® SGX Instructions with Segmentation

The Intel SGX leaf functions used for entering the enclave (ENCLU[EENTER] and ENCLU[ERESUME]) ensure that all usable segment registers except for FS and GS have a zero base.

Additionally they save the existing contents of the FS/GS segment registers (including the hidden portion) in the processor, and load those registers with new values compatible with enclave security. The instructions also ensure that the linear ranges and access rights available under the newly-loaded FS and GS abide to OS policies by ensuring they are subsets of the linear-address range and access rights available for the DS segment. See EENTER Leaf and ERESUME Leaf in Chapter 41 for exact details of this computation.

Any exit from the enclave either via ENCLU[EEXIT] or via an AEX restores the saved values of FS/GS segment registers.

The enclave-entry leaf functions also ensure that the CS segment mode (64-bit, compatible, or 32 bit modes) is consistent with the segment mode for which the enclave was created, as indicated by the SECS.ATTRIBUTES.MODE64 bit, and that the CPL of the logical processor is 3.

Finally, all leaf functions of ENCLU and ENCLS instructions require that the DS segment be usable, and be an expand-up segment. Failing this check results in generation of a #GP(0) exception.

42.3.4 Interactions of Enclave Execution with Segmentation

During the course of execution, enclave code abides by all segmentation policies as dictated by IA32 and Intel 64 Architectures, and generates appropriate exceptions on violations.

Additionally, any attempt by software executing inside an enclave to modify the processor's segmentation state (e.g. via MOV seg register, POP seg register, LDS, far jump, etc.) results in the generation of a #UD. See Section 39.6.1 for more information.

Upon enclave entry via the EENTER leaf function, FS is loaded from the TCS.OFSBASGX and TCS.FSLIMIT fields and GS is loaded from the TCS.OGSBASGX and TCS.GSLIMIT fields. An asynchronous exit saves FSBASE and GSBASE into the current SSA frame. Execution of WRFSBASE and WRGSBASE from inside a 64-bit enclave does not generate the #UD exception. If the software running inside an enclave modifies the segment-base values for these registers using the WRFSBASE and WRGSBASE instructions, the new values are saved into the current SSA frame on an asynchronous enclave exit (AEX) and restored back on enclave entry via ENCLU[ERESUME] instruction.

42.4 INTERACTIONS WITH PAGING

Intel SGX instructions are available only when the processor is executing in a protected mode of operation. Additionally, all Intel SGX leaf functions except for EDBGRD and EDBGWR are available only if paging is enabled. Any attempt to execute these leaf functions with paging disabled results in delivery of #UD to the system software (OS or VMM). As with segmentation, enclaves abide by all the paging policies set up by the OS, but they can be more restrictive than the OS.

All the memory operands passed into Intel SGX instructions are interpreted as offsets within the data segments, and the linear addresses generated by combining these offsets with DS segment register are subject to paging-based access control, if paging is enabled at the time of the execution of the leaf function.

Since the ENCLU[EENTER] and ENCLU[EEXIT] can only be executed when paging is enabled, and since paging cannot be disabled by software running inside an enclave (recall that enclaves always run with CPL of 3), enclave execution is always subject to paging-based access control. The Intel SGX access control itself is implemented as an extension to the three paging modes of Intel Architecture. See Section 38.5 for details.

It should be noted that Intel SGX instructions may set the Accessed and Dirty flags of the referenced page table entries of non-faulting EPC pages, although the instruction may eventually fault due to some other reason.

42.5 INTERACTIONS WITH VMX

Intel SGX functionality (including SGX1 and SGX2) can be made available to software running in either VMX-root or VMX-non-root mode, as long as

- The software is not running in SMM mode of operation.
- The software is using a legal mode of operation (see Section 42.1).

A VMM has the flexibility to configure the VMCS to permit a guest to use the entirety of the ENCLS leaf functions or any sub-set of the ENCLS leaf functions at the granularity of individual leaf function. Availability of the ENCLU leaf functions in VMX non-root operation has the same requirement as ENCLU leaf functions outside of a virtualized environment.

Enhancement in the VMCS to allow configurability for Intel SGX in a guest is enumerated by VMX capability MSRs. A summary of the enumerated capabilities is listed in Table 42-1.

Table 42-1. Summary of VMX Capability Enumeration MSRS for Processors Supporting Intel® SGX

Interface	Description
IA32_VMX_PROCBASED_CTLS2[bit 15]	f 1, indicates that 1-setting "enable ENCLS exiting" in the secondary processor-based VM-execution control is allowed. Mirrors the value of CPUID.(EAX=07H, ECX=0).EBX.SGX
IA32_VMX_MISC[bit 30]	If 1, VM entry checks that the VM-entry instruction length is in the range 0-15. See Section 42.5.3.

Details of the VMCS control to allow VMM to configure support of Intel SGX in guest operation is described in Section 42.5.1

42.5.1 VMM Controls to Configure Guest Support of Intel® SGX

Intel SGX capabilities are primarily exposed to the software via the CPUID instruction. VMMs can virtualize CPUID instruction to expose/hide this capability to/from guests.

Some of Intel SGX resources are exposed/controlled via model-specific registers (see Section 37.7). VMMs can virtualize these MSRs for the guests using standard RDMSR/WRMSR hooks.

The VMM can partition the Enclave Page Cache, and assign various partitions to (a subset of) its guests via the usual memory-virtualization techniques such as EPTs or shadow page tables.

The VMM can set the "enable ENCLS exiting" (bit 15 in the secondary processor-based VM-execution controls) to cause a VM-Exit when the ENCLS instruction is executed in VMX non-root operation. Support for the 1-setting of this control will be enumerated in the VMX capability MSRs (see Section 42.5.1.1).

If the "enable ENCLS exiting" control is 0 on a VM entry, all of the ENCLS leaf functions are permitted in VMX non-root operation.

If the "enable ENCLS exiting" control is 1, execution of ENCLS leaf functions in VMX non-root operation is governed by consulting the bits in a new 64-bit VM-execution control called "ENCLS-exiting bitmap" (VMCS field encoding 0202EH).

When bits in the "ENCLS-exiting bitmap" are set, execution of the corresponding ENCLS leaf functions in VMX non-root operation causes a VM exit.

The priority of "ENCLS-exiting bitmap" check is immediately below the CPL check. This field exists only on processors that support the 1-setting of "enable ENCLS exiting".

Processors that do not support Intel SGX, i.e. CPUID.(EAX=07H, ECX=0):EBX.SGX = 0, the following items hold:

- VMX capability MSRS enumerate the 1-setting of "enable ENCLS exiting" as not supported.
- VM entries with "enable ENCLS exiting" field set to 1 will fail.
- VMREAD/VMWRITE of the "ENCLS-exiting bitmap" will fail.

42.5.1.1 Guest State Area - Guest Non-Register State

Table 42-2. Guest Interruptibility State

Position	Field	Value
0	Blocking by STI	See Chapter 24 of *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3C*
1	Blocking by MOV SS	See Chapter 24 of *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3C*
2	Blocking by SMI	See Chapter 24 of *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3C*
3	Blocking by NMI	See Chapter 24 of *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3C*
4	ENCLAVE_INTERRUPTION	See Section 42.5.3.3

42.5.1.2 VM-Execution Controls

VM-Execution controls related to Intel SGX include a 64-bit ENCLS-exiting bitmap (VMCS field encoding 0202EH) and the "Enable ENCLS exiting" control at bit 15 of the secondary processor based VM execution controls. The ENCLS-exiting bitmap provides bit fields for VMM to control whether individual ENCLS leaf functions cause a VM exit when run in VMX non-root operation, see "ENCLS—Execute an Enclave System Function of Specified Leaf Number" in Section 41.1.1. If bit 31 of the primary processor-based VM execution controls is 0, the processor functions as if the Enable ENCLS Exiting bit was set to 0.

Table 42-3. Secondary Processor Based VM Execution Controls

Position	Field	Value
14:0	See Chapter 24 of *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3C*	
15	Enable ENCLS exiting	Enable ENCLS-exiting bitmap for ENCLS leaf functions
31:16	See Chapter 24 of *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3C*	

42.5.1.3 Basic VM-Exit Information

Bit 27 of the VM-exit information field provides information on VM exits due to the interaction between enclave and asynchronous events.

Table 42-4. Format of Exit Reason

Bit Position	Value
15:0	Basic exit reason: See Chapter 24 of *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3C*
26:16	Reserved: See Chapter 24 of *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3C*
27	ENCLAVE_INTERRUPTION: see Section 42.5.2
31:28	See Chapter 24 of *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3C*

The encodings of Basic Exit Reason can indicate if the VM exit is related to executing ENCLS leaf functions.

60	ENCLS

42.5.2 VM Exits While Inside an Enclave

VM exits that originate within an enclave set the following two bits before delivering the VM exit to the VMM:

- Bit 27(Enclave Interruption) in the Exit reason filed of Basic VM-exit information.
- Bit 4 (Enclave Interruption) in the Interruptibility State of Guest Non-Register State of VMCS (field encoding 4824H, Table 42-2).

Any VM exit (except for failed VM-entry VM exit) that sets ENCLAVE_INTERRUPTION in GUEST_INTERRUPTIBILITY state, also sets Enclave Interruption in the EXIT_REASON field.

VM exit conditions include:

- Direct VM exits caused by exceptions, interrupts, and NMIs that happen while the logical processor is executing inside an enclave.
- Indirect VM exits triggered by interrupts, exceptions, and NMIs that happen while the logical processor is executing inside an enclave.
  - This includes VM exits encountered during vectoring due to EPT violations, task switch, etc.
- Parallel VM exits caused by SMI that is received while the logical processor is executing inside an enclave.
- All other VM exits that happen on an instruction boundary that is inside an enclave.

IA32/Intel 64 Architectures define very strict priority ordering between classes of events that are received on the same instruction boundary, and such ordering requires careful attention to cross-interactions between events. See Section 42.6 for details of interactions of architecturally visible events with Intel SGX architecture.

All processor states saved in the VMCS on VM exits from an enclave contain synthetic state. See Table 40-1 and Table 40-2 for details of the state saved into the VMCS.

A failed VM-entry VM exit will not set the ENCLAVE_INTERRUPTION bit in the EXIT_REASON field but since it does not modify the guest state area, the original value of the ENCLAVE_INTERRUPTION bit remains untouched in the guest's Interruptibility State field.

42.5.3 VM Entry Consistency Checks and Intel® SGX

A VM entry performs consistency checks according to those described in Chapter 26 of the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3C*.

42.5.3.1 VM-Entry Instruction-Length Field

Additionally, to facilitate event injection following an AEX for which the instruction length field is cleared, VM entry allows the VM-entry instruction-length field to hold the value 0 if the following items all hold true:

- IA32_VMX_MISC[30] is set to 1.
- The valid bit (bit 31) of the VM-entry interruption-information field in the current VMCS is 1.
- The interruption type (bits 10:8)of the VM-entry interruption-information field has value 4 (software interrupt), 5 (privileged software exception), or 6 (software exception).

42.5.3.2 VM Execution Control Setting Checks

VM-entry consistency check on VM-execution control fields includes:

- If CPUID.(EAX=07H, ECX=0):EBX.SGX = 0, and if the "ENCLS Exiting" control (bit 15 in the secondary processor-based VM-execution controls) is set, then the VM entry fails, which sets RFLAGS.ZF=1 and error code=7 (VM entry with invalid control field).

42.5.3.3 Guest Interruptibility State Checks

If the Enclave Interruption bit in the guest non-register state's interruptibility state field is set and CPUID.(EAX=07H, ECX=0):EBX.SGX = 0, VM entry fails with the "VM-entry failure due to invalid guest state" error (error code 33).

If both the "Blocking by MOV SS" and Enclave Interruption bits are set in the Interruptibility-State field in the guest-state area of the VMCS, VM entry fails with the "VM-entry failure due to invalid guest state" error (error code

33). Note that, since the MOV SS and POP SS instructions are illegal inside an enclave, no VM exit will set the interruptibility-state field with both bits set.

If the Enclave Interruption bit is set in the interruptibility-state field in the guest Non-Register state of the VMCS, and a VM entry leads to a VMEXIT during event injection, then the VM exit sets the Enclave Interruption bit as described in Section 42.5.2. Such a transition does not include an asynchronous enclave exit and consequently, neither the processor's architectural state, nor the state saved in the guest-state area of the VMCS is synthesized as is done during asynchronous enclave exits (for example: there is no clearing of the GPRs or of VMCS fields such as the VM-exit instruction length or the low 12 bits in certain address fields in the VMCS).

42.5.4 Interaction of Intel® SGX with Various VMMs

If IA32_VMX_MISC.[bit 30] = 0, permitted VM entry instruction lengths are 1-15 bytes. If IA32_VMX_MISC.[bit 30] = 1, permitted VM entry instruction lengths allow 0 as a legal value for interruption type 4(software interrupt), 5 (privileged software exception), or 6 (software exception).

Support for an instruction length of 0 simplifies the work for a VMM that wishes to inject an event back to the guest after an AEX occurred in the guest and the instruction length field has been cleared out.

42.5.5 Interactions with EPTs

Intel SGX instructions are fully compatible with Extended Page Tables.

All the memory operands passed into Intel SGX instructions are interpreted as offsets within the data segments, and the linear addresses generated by combining these offsets with DS segment register are subject to paging and EPT-based access control. As with paging, enclaves abide by all the EPT policies set up by the VMM, but they can be more restrictive than the OS.

The Intel SGX access control itself is implemented as an extension to the IA paging and EPT mechanisms. See Section 42.4 for details of this extension.

Intel SGX instructions may set Accessed and Dirty flags of the referenced extended page table entries (when supported) on non-faulting EPC pages, although the instruction may eventually fault due to some other reason.

42.5.6 Interactions with APIC Virtualization

The Intel SGX architecture interacts with APIC virtualization due to its interactions with the APIC access page as well as Virtual APIC Page. See Section 42.11.1 for the interactions of Intel SGX architecture with the APIC Access Page.

42.5.7 Interactions with Monitor Trap Flag

The interactions of Intel SGX with the Monitor Trap Flag are documented in Section 43.2.

42.5.8 Interactions with Interrupt-Virtualization Features and Events

If software is executing in an enclave and a VM exit would occur that would report “interrupt window” as basic exit reason (due to the 1-setting of the “interrupt window exiting” VM-execution control), an AEX occurs before the VM exit is delivered.

If software is executing in an enclave and a virtual interrupt would be delivered through the IDT (due to the 1-setting of the “virtual interrupt delivery” VM-execution control), an AEX occurs before delivery of the virtual interrupt.

If software is executing in an enclave and an external interrupt arrives that would cause a VM exit (due to the 1-setting of the “external interrupt exiting” VM-execution control), an AEX occurs before the VM exit is delivered.

If software is executing in an enclave and an external interrupt arrives that would cause virtual interrupts to be posted to the virtual-IRR field in the virtual-APIC page (due to the 1-setting of the “process posted interrupts” VM-

execution control), an AEX may or may not occur before the posting of the virtual interrupts. This behavior is implementation specific.

42.6 INTEL® SGX INTERACTIONS WITH ARCHITECTURALLY-VISIBLE EVENTS

All architecturally visible vectored events (IA32 exceptions, interrupts, SMI, NMI, INIT, VM exit) that are detected while inside an enclave cause an asynchronous enclave exit. Additionally, INT3, and the SignalTXTMsg[SENTER] (i.e. GETSEC[SENTER]'s rendezvous event message) events also cause asynchronous enclave exits. Note that SignalTXTMsg[SEXIT] (i.e. GETSEC[SEXIT]'s teardown message) does not cause an AEX.

On an AEX, information about the event causing the AEX is stored in the SSA (see Section 40.4 for details of AEX). The information stored in the SSA only describes the first event that triggered the AEX. If parsing/delivery of the first event results in detection of further events (e.g. VM exit, double fault, etc.), then the event information in the SSA is not updated to reflect these subsequently detected events.

42.7 INTERACTIONS WITH THE PROCESSOR EXTENDED STATE AND MISCELLANEOUS STATE

42.7.1 Requirements and Architecture Overview

Processor extended states are the ISA features that are enabled by the settings of CR4.OSXSAVE and the XCR0 register. Processor extended states are normally saved/restored by software via XSAVE/XRSTOR instructions. Details of discovery of processor extended states and management of these states are described in CHAPTER 13 of *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3A*.

Additionally, the following requirements apply to Intel SGX:

- On an AEX, the Intel SGX architecture must protect the processor extended state and miscellaneous state in the state-save area (SSA), and clear the secrets from the processor extended state that is used by an enclave.
- Intel SGX architecture must ensure that erroneous XCR0 and/or XBV_HEADER settings by system software do not result in SSA overflow.
- Enclave software should be able to discover only those processor extended state and miscellaneous state for which such protection is enabled.
- The processor extended states that are enabled inside the enclave must form an integral part of the enclave's identity. This requirement has two implications:
  - Certain processor extended state (e.g., Memory Protection Extensions, see Chapter 9 of *Intel® Architecture Instruction Set Extensions Programming Reference*) modify the behavior of the legacy ISA software. If such features are enabled for enclaves that do not understand those features, then such a configuration could lead to a compromise of the enclave's security.
  - Service providers may decide to assign different trust level to the same enclave depending on the ISA features the enclave is using.

To meet these requirements, the Intel SGX architecture defines a sub-field called X-Feature Request Mask (XFRM) in the ATTRIBUTES field of the SECS. On enclave entry, after certain consistency checks, the value in the XCR0 is saved internally by the processor, and is replaced by the XFRM. On enclave exit, the original value of XCR0 is restored. Consequently, while inside the enclave, the processor extended states enabled in XFRM are in enabled state, and those that are disabled in XFRM are in disabled state. The entire ATTRIBUTES field, including the XFRM subfield is integral part of enclave's identity (i.e., its value is included in reports generated by ENCLU[EREPORT], and select bits from this field can be included in key-derivation for keys obtained via ENCLU[EGETKEY]).

Enclave developers can create their enclave to work with certain features and fallback to another code path in case those features aren't available (e.g. optimize for AVX and fallback to SSE). For this purpose Intel SGX provides the following fields in SIGSTRUCT: ATTRIBUTES, ATTRIBUTESMASK, MISCSELECT, and MISCMASK. EINIT ensures that the final SECS.ATTRIBUTES and SECS.MISCSELECT comply with the enclave developer's requirements as follows:

SIGSTRUCT.ATTRIBUTES & SIGSTRUCT.ATTRIBUTEMASK = SECS.ATTRIBUTES & SIG-STRUCT.ATTRIBUTEMASK

SIGSTRUCT.MISCSELECT & SIGSTRUCT.MISCMASK = SECS.MISCSELECT & SIG-STRUCT.MISCMASK.

On an asynchronous enclave exit, the processor extended states enabled by XFRM are saved in the current SSA frame, and overwritten by synthetic state (see Section 40.3 for the definition of the synthetic state). When the interrupted enclave is resumed via ENCLU[ERESUME], the saved state for processor extended states enabled by XFRM is restored.

42.7.2 Relevant Fields in Various Data Structures

42.7.2.1 SECS.ATTRIBUTES.XFRM

The ATTRIBUTES field of the SECS data structure (see Section 38.7) contains a sub-field called X-Feature Request Mask (XFRM). Software populates this field at the time of enclave creation indicating the processor extended state configuration required by the enclave.

Intel SGX architecture guarantees that during enclave execution, the processor extended state configuration of the processor is identical to what is required by the XFRM sub-field. All the processor extended states enabled in XFRM are saved on AEX from the enclave and restored on ERESUME.

The XFRM sub-field has the same layout as XCR0, and has consistency requirements that are similar to those for XCR0. Specifically, the consistency requirements on XFRM values depend on the processor implementation and the set of features enabled in CR4.

Legal values for SECS.ATTRIBUTES.XFRM conform to these requirements:

- XFRM[1:0] must be set to 0x3.
- If the processor does not support XSAVE, or if the system software has not enabled XSAVE, then XFRM[63:2] must be zero.
- If the processor does support XSAVE, XFRM must contain a value that would be legal if loaded into XCR0.

The various consistency requirements are enforced at different times in the enclave's life cycle, and the exact enforcement mechanisms are elaborated in Section 42.7.3 through Section 42.7.6.

On processors not supporting XSAVE, software should initialize XFRM to 0x3. On processors supporting XSAVE, software should initialize XFRM to be a subset of XCR0 that would be present at the time of enclave execution. Because bits 0 and 1 of XFRM must always be set, the use of Intel SGX requires that SSE be enabled (CR4.OSFXSR = 1).

42.7.2.2 SECS.SSAFRAMESIZE

The SSAFRAMESIZE field in the SECS data structure specifies the number of pages which software allocated[1] for each SSA frame, including both the GPRSGX area, MISC area, the XSAVE area (x87 and XMM states are stored in the latter area), and optionally padding between the MISC and XSAVE area. The GPRSGX area must hold all the general-purpose registers, additional Intel SGX specific information, the MISC area must hold the Miscellaneous state as specified by SECS.MISCSELECT, the XSAVE area holds the set of processor extended states specified by SECS.ATTRIBUTES.XFRM (see Section 38.9 for the layout of SSA and Section 42.7.3 for ECREATE's consistency checks). The SSA is always in non-compacted format.

If the processor does not support XSAVE, the XSAVE area will always be 576 bytes; a copy of XFRM (which will be set to 0x3) is saved at offset 512 on an AEX.

If the processor does support XSAVE, the length of the XSAVE area depends on SECS.ATTRIBUTES.XFRM. The length would be equal to what CPUID.(EAX=0DH, ECX= 0):EBX returns if XCR0 were set to XFRM. The following pseudo code illustrates how software can calculate this length using XFRM as the input parameter without modi-fying XCR0:

```
offset = 576;
size_last_x = 0;
For x=2 to 63
IF (XFRM[x] != 0) Then
```

1. It is the responsibility of the enclave to actually allocate this memory.

```
    tmp_offset = CPUID.(EAX=0DH, ECX= x):EBX[31:0];
    IF (tmp_offset >= offset + size_last_x) Then
        offset = tmp_offset;
        size_last_x = CPUID.(EAX=0DH, ECX= x):EAX[31:0];
    FI;
FI;
EndFor
return (offset + size_last_x); (* compute_xsave_size(XFRM), see "ECREATE—Create an SECS page in the Enclave Page Cache"*)
```

Where the non-zero bits in XFRM are a subset of non-zero bit fields in XCR0.

42.7.2.3 XSAVE Area in SSA

The XSAVE area of an SSA frame begins at offset 0 of the frame.

42.7.3 Processor Extended States and ENCLS[ECREATE]

The ECREATE leaf of the ENCLS instruction enforces a number of consistency checks described earlier. The execution of ENCLS[ECREATE] instruction results in a #GP(0) exception in any of the following cases:

- SECS.ATTRIBUTES.XFRM[1:0] is not 3.
- The processor does not support XSAVE and any of the following is true:
  - SECS.ATTRIBUTES.XFRM[63:2] is not 0.
  - SECS.SSAFRAMESIZE is 0.
- The processor supports XSAVE and any of the following is true:
  - XSETBV would fault on an attempt to load XFRM into XCR0.
  - XFRM[63]=1.
  - The SSAFRAME is too small to hold required, enabled states (see Section 42.7.2.2).

42.7.4 Processor Extended States and ENCLU[EENTER]

42.7.4.1 Fault Checking

The EENTER leaf function of the ENCLU instruction enforces a number of consistency requirements described earlier. The execution of the ENCLU[EENTER] leaf function results in a #GP(0) exception in any of the following cases:

- If CR4.OSFXSR=0.
- If The processor supports XSAVE and either of the following is true:
  - CR4.OSXSAVE=0 and SECS.ATTRIBUTES.XFRM is not 3.
  - (SECS.ATTRIBUTES.XFRM & XCR0) != SECS.ATTRIBUTES.XFRM

42.7.4.2 State Loading

If ENCLU[EENTER] is successful, the current value of XCR0 is saved internally by the processor and replaced by SECS.ATTRIBUTES.XFRM.

42.7.5 Processor Extended States and AEX

42.7.5.1 State Saving

On an AEX, processor extended states are saved into the XSAVE area of the SSA frame in a compatible format with XSAVE that was executed with EDX:EAX = SECS.ATTRIBUTES.XFRM, with the memory operand being the XSAVE area, and (for 64-bit enclaves) as if REX.W=1. The XSTATE_BV part of the XSAVE header is saved with 0 for every bit that is 0 in XFRM. Other bits may be saved as 0 if the state saved is initialized.

Note that enclave entry ensures that if CR4.OSXSAVE is set to 0, then SECS.ATTRIBUTES.XFRM is set to 3. It should also be noted that it is not possible to enter an enclave with FXSAVE disabled.

42.7.5.2 State Synthesis

After saving the extended state, the processor restores XCR0 to the value it held at the time of the most recent enclave entry.

The state of features corresponding to bits set in XFRM is synthesized. In general, these states are initialized. Details of state synthesis on AEX are documented in Section 40.3.1.

42.7.6 Processor Extended States and ENCLU[ERESUME]

42.7.6.1 Fault Checking

The ERESUME leaf function of the ENCLU instruction enforces a number of consistency requirements described earlier. Specifically, the ENCLU[ERESUME] leaf function results in a #GP(0) exception in any of the following cases:

- CR4.OSFXSR=0.
- The processor supports XSAVE and either of the following is true:
  - CR4.OSXSAVE=0 and SECS.ATTRIBUTES.XFRM is not 3.
  - (SECS.ATTRIBUTES.XFRM & XCR0) != SECS.ATTRIBUTES.XFRM.

A successful execution of ENCLU[ERESUME] loads state from the XSAVE area of the SSA frame in a fashion similar to that used by the XRSTOR instruction. Data in the XSAVE area that would cause the XRSTOR instruction to fault will cause the ENCLU[ERESUME] leaf function to fault. Examples include, but are not restricted to the following:

- A bit is set in the XSTATE_BV field and clear in XFRM.
- The required bytes in the header are not clear.
- Loading data would set a reserved bit in MXCSR.

Any of these conditions will cause ERESUME to fault, even if CR4.OSXSAVE=0.

42.7.6.2 State Loading

If ENCLU[ERESUME] is successful, the current value of XCR0 is saved internally by the processor and replaced by SECS.ATTRIBUTES.XFRM.

State is loaded from the XSAVE area of the SSA frame as if the XRSTOR instruction were executed with XCR0=XFRM, EDX:EAX = XFRM, with the memory operand being the XSAVE area, and (for 64-bit enclaves) as if REX.W=1.

ENCLU[ERESUME] ensures that a subsequent execution of XSAVEOPT inside the enclave will operate properly (e.g., by marking all state as modified).

42.7.7 Processor Extended States and ENCLU[EEXIT]

The ENCLU[EEXIT] leaf function does not perform any X-feature specific consistency checks, nor performs any state synthesis. It is the responsibility of enclave software to clear any sensitive data from the registers before

executing EEXIT. However, successful execution of the ENCLU[EEXIT] leaf function restores XCR0 to the value it held at the time of the most recent enclave entry.

42.8 INTERACTIONS WITH SMM

42.8.1 Availability of Intel® SGX instructions in SMM

Enclave instructions are not available in SMM, and any attempt to execute ENCLS or ENCLU instructions inside SMM results in a #UD exception.

42.8.2 SMI while Inside an Enclave

The response to an SMI received while executing inside an enclave depends on whether the dual-monitor treatment is enabled. For detailed discussion of transfer to SMM, see Chapter 34, "System Management Mode" of the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3C*.

If the logical processor executing inside an enclave receives an SMI when dual-monitor treatment is not enabled, the logical processor exits the enclave asynchronously, and transfers the control to the SMM handler. In addition to saving the synthetic architectural state to the SMRAM State Save Map (SSM), the logical processor also sets the "Enclave Interruption" bit in the SMRAM SSM (bit position 1 in SMRAM field at offset 7EE0H).

If the logical processor executing inside an enclave receives an SMI when dual-monitor treatment is enabled, the logical processor exits the enclave asynchronously, and transfers the control to the SMM monitor via SMM VM exit. The SMM VM exit sets the "Enclave Interruption" bit in the Exit Reason (see Table 42-4) and in the Guest Interruptibility State field (see Table 42-2) of the SMM transfer VMCS.

42.8.3 SMRAM Synthetic State of AEX Triggered by SMI

All processor registers saved in the SMRAM have the same synthetic values listed in Section 40.3. Additional SMRAM fields that are treated specially on SMI are:

Table 42-6. SMRAM Synthetic States on Asynchronous Enclave Exit

Position	Field	Value	Writable
SMRAM Offset 07EE0H.Bit 1	ENCLAVE_INTERRUPTION	Set to 1 if exit occurred in enclave mode	No

42.9 INTERACTIONS OF INIT, SIPI, AND WAIT-FOR-SIPI WITH INTEL® SGX

INIT received inside an enclave, while the logical processor is not in VMX operation, causes the logical processor to exit the enclave asynchronously. After the AEX, the processor's architectural state is initialized to "Power-on" state (Table 9.1 in *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3A*). If the logical processor is BSP, then it proceeds to execute the BIOS initialization code. If the logical processor is an AP, it enters Wait-for-SIPI (WFS) state.

INIT received inside an enclave, while the logical processor (LP) is in VMX-root operation, follows regular Intel Architecture behavior and is blocked.

INIT received inside an enclave, while the logical processor is in VMX-non-root operation, causes an AEX. Subsequent to the AEX, the INIT is delivered to the VMM via appropriate VM exit with the Enclave Interruption bit in the VMCS.EXIT_REASON set.

A processor cannot be inside an enclave in the WFS state. Consequently, a SIPI received while inside an enclave is lost.

Intel SGX does not change the behavior of the processor in the WFS state.

The SGX-related processor states after INIT-SIPI-SIPI is as follows:

- EPCM: Unchanged
- CPUID.LEAF_12H.*: Unchanged
- ENCLAVE_MODE: 0 (LP exits enclave asynchronously)
- MEE state: Unchanged

Software should be aware that following INIT-SIPI-SIPI, the EPC might contain valid pages and should take appropriate measures such as initialize the EPC with the EREMOVE leaf function.

42.10 INTERACTIONS WITH DMA

DMA is not allowed to access any Processor Reserved Memory.

42.11 INTERACTIONS WITH MEMORY CONFIGURATION AND VARIOUS MEMORY RANGES

42.11.1 Interactions of Intel® SGX with APIC Access Address

A memory access by an enclave instruction that implicitly uses a cached physical address is never checked for overlap with the APIC-access page. Such accesses never cause APIC-access VM exits and are never redirected to the virtual-APIC page. Implicit memory accesses can only be made to the SECS, the TCS, or the SSA of an enclave (see Section 38.3).

An explicit Enclave Access (a linear memory access which is either from within an enclave into it ELRANGE, or an access by an Intel SGX instruction that is expected to be in the EPC) that overlaps with the APIC-access page causes a #PF exception (APIC page is expected to be outside of EPC).

Non-Enclave accesses made either by an Intel SGX instruction or by a logical processor inside an enclave to an address that without SGX would have caused redirection to the virtual-APIC page instead cause an APIC-access VM exit.

Other than implicit accesses made by Intel SGX instructions, guest-physical and physical accesses are not considered “enclave accesses”; consequently, such accesses results in abort-page semantics if these accesses eventually reach EPC. This applies to any non-enclave physical accesses.

While a logical processor inside an enclave, the checking of the instruction pointer's linear address against the enclave's linear-address range (ELRANGE) is done before checking the physical address to which the linear address translates against the APIC-access page. Thus, an attempt to execute an instruction outside ELRANGE, the instruction fetch results in a #GP(0), even if the linear address would translate to a physical address overlaps the APIC-access page.

42.12 INTERACTIONS WITH TXT

42.12.1 Enclaves Created Prior to Execution of GETSEC

Enclaves which have been created before the GETSEC[SENTER] instruction are available for execution after the successful completion of GETSEC[SENTER] and the corresponding SINIT ACM. Actions that TXT launched environment performs in preparation to execute code which also applies to enclave code to run after GETSEC[SENTER].

42.12.2 Interaction of GETSEC with Intel® SGX

All leaf functions of the GETSEC instruction are illegal inside an enclave, and result in #UD.

Responding Logical Processors (RLP) which are executing inside an enclave at the time a GETSEC[SENTER] event occurs perform an AEX from the enclave and then enter the Wait-for-SIPI state.

RLP executing inside an enclave at the time of GETSEC[SEXIT], behave as defined for GETSEC[SEXIT]-that is, the RLPs pause during execution of SEXIT and resume after the completion of SEXIT.

The execution of a TXT launch does not affect Intel SGX configuration or security parameters.

42.12.3 Interactions with Authenticated Code Modules (ACMs)

After execution of any non-faulting Intel SGX instructions, the Intel SGX architecture forbids the launching of ACMs with Intel SGX SVN that is lower than the expected Intel SGX SVN threshold that was specified by BIOS. The non-faulting Intel SGX instructions refer to Intel SGX instruction leaves that do not return error code and executed successfully without causing an exception. Intel SGX provides interfaces for system software to discover whether a non faulting Intel SGX instruction has been executed, and evaluate the suitability of the Intel SGX SVN value of any ACM that is expected to be launched by the OS or the VMM.

These interfaces are provided through a read-only MSR called the IA32_SGX_SVN_STATUS MSR (MSR address 500h). The IA32_SGX_SVN_STATUS MSR has the format shown in Table 42-7.

Table 42-7. Layout of the IA32_SGX_SVN_STATUS MSR

Bit Position	Name	ACM Module ID	Value
0	Lock	N.A.	• If 1, indicates that a non-faulting Intel SGX instruction has been executed, consequently, launching a properly signed ACM but with Intel SGX SVN value less than the BIOS specified Intel SGX SVN threshold would lead to an TXT shutdown. • If 0, indicates that the processor will allow a properly signed ACM to launch irrespective of the Intel SGX SVN value of the ACM.
15:1	RSVD	N.A.	0
23:16	SGX_SVN_SINIT	SINIT ACM	• If CPUID.01H:ECX.SMX =1, this field reflects the expected threshold of Intel SGX SVN for the SINIT ACM. • If CPUID.01H:ECX.SMX =0, this field is reserved (0).
63:24	RSVD	N.A.	0

OS/VMM that wishes to launch an architectural ACM such as SINIT is expected to read the IA32_SGX_SVN_STATUS MSR. If the Intel SGX SVN value reported in the corresponding component of the IA32_SGX_SVN_STATUS is greater than the Intel SGX SVN value in the ACM's header, and if bit 0 of IA32_SGX_SVN_STATUS is 1, then the OS/VMM should not launch that version of the ACM. It should obtain an updated version of the ACM either from the BIOS or from an external resource. If either the Intel SGX SVN of the ACM is greater than the value reported by IA32_SGX_SVN_STATUS, or the lock bit in the IA32_SGX_SVN_STATUS is not set, then the OS/VMM can safely launch the ACM. However, OSVs/VMMs are strongly advised to update their version of the ACM any time they detect that the Intel SGX SVN of the ACM carried by the OS/VMM is lower than that reported by IA32_SGX_SVN_STATUS MSR, irrespective of the setting of the lock bit.

42.13 INTERACTIONS WITH CACHING OF LINEAR-ADDRESS TRANSLATIONS

Entering and exiting an enclave causes the logical processor to flush all the global linear-address context as well as the linear-address context associated with the current VPID and PCID. The MONITOR FSM is also cleared.

42.14 INTERACTIONS WITH INTEL® TRANSACTIONAL SYNCHRONIZATION EXTENSIONS (INTEL® TSX)

1. ENCLU or ENCLS instructions inside an HLE region will cause the flow to be aborted and restarted non-speculatively. ENCLU or ENCLS instructions inside an RTM region will cause the flow to be aborted and transfer control to the fallback handler.

2. If XBEGIN is executed inside an enclave, the processor does NOT check whether the address of the fallback handler is within the enclave.

3. If an RTM transaction is executing inside an enclave and there is an attempt to fetch an instruction outside the enclave, the transaction is aborted and control is transferred to the fallback handler. No #GP is delivered.

4. If an RTM transaction is executing inside an enclave and there is a data access to an address within the enclave that denied due to EPCM content (e.g., to a page belonging to a different enclave), the transaction is aborted and control is transferred to the fallback handler. No #GP is delivered.

5. If an RTM transaction executing inside an enclave aborts and the address of the fallback handler is outside the enclave, a #GP is delivered after the abort (EIP reported is that of the fallback handler).

42.14.1 HLE and RTM Debug

RTM debug will be suppressed on opt-out enclave entry. After opt-out entry, the logical processor will behave as if IA32_DEBUG_CTL[15]=0. Any #DB detected inside an RTM transaction region will just cause an abort with no exception delivered. After opt-in entry, if either DR7[11] = 0 OR IA32_DEBUGCTL[15] = 0, any #DB or #BP detected inside an RTM transaction region will just cause an abort with no exception delivered. After opt-in entry, if DR7[11] = 1 AND IA32_DEBUGCTL[15] = 1, any #DB or #BP detected inside an RTM translation will terminate speculative execution, set RIP to the address of the XBEGIN instruction, and be delivered as #DB (any #BP is converted to #DB) - imply an Intel SGX AEX. DR6[16] will be cleared, indicating RTM debug (if the #DB causes a VM exit, DR6 is not modified but bit 16 of the pending debug exceptions field in the VMCS will be set).

42.15 INTEL® SGX INTERACTIONS WITH S STATES

Whenever an Intel SGX enabled processor leaves the S0 or S1 state for S2-S5 state, enclaves are destroyed. This is due to the EPC being destroyed when power down occurs.

42.16 INTEL® SGX INTERACTIONS WITH MACHINE CHECK ARCHITECTURE (MCA)

42.16.1 Interactions with MCA Events

All architecturally visible machine check events (#MC and CMCI) that are detected while inside an enclave cause an asynchronous enclave exit.

Any machine check exception (#MC) that occurs after Intel SGX is first enables causes Intel SGX to be disabled, (CPUID.SGX_Leaf.0:EAX[SGX1] == 0). It cannot be enabled until after the next reset.

42.16.2 Machine Check Enables (IA32_MCi_CTL)

All supported IA32_MCi_CTL bits for all the machine check banks must be set for Intel SGX to be available (CPUID.SGX_Leaf.0:EAX[SGX1] == 1). Any act of clearing bits from '1 to '0 in any of the IA32_MCi_CTL register may disable Intel SGX (set CPUID.SGX_Leaf.0:EAX[SE1] to 0) until the next reset.

42.16.3 CR4.MCE

CR4.MCE can be set or cleared with no interactions with Intel SGX.

42.17 INTEL® SGX INTERACTIONS WITH PROTECTED MODE VIRTUAL INTERRUPTS

ENCLS[EENTER] modifies neither EFLAGS.VIP nor EFLAGS.VIF.

ENCLS[ERESUME] loads EFLAGS in a manner similar to that of an execution of IRET with CPL = 3. This means that ERESUME modifies neither EFLAGS.VIP nor EFLAGS.VIF regardless of the value of the EFLAGS image in the SSA frame.

AEX saves EFLAGS.VIP and EFLAGS.VIF unmodified into the EFLAGS image in the SSA frame. AEX modifies neither EFLAGS.VIP nor EFLAGS.VIF after saving EFLAGS.

If CR4.PVI = 1, CPL = 3, EFLAGS.VM = 0, IOPL < 3, EFLAGS.VIP = 1, and EFLAGS.VIF = 0, execution of STI causes a #GP fault. In this case, STI modifies neither EFLAGS.IF nor EFLAGS.VIF. This behavior applies without change within an enclave (where CPL is always 3). Note that, if IOPL = 3, STI always sets EFLAGS.IF without fault; CR4.PVI, EFLAGS.VIP, and EFLAGS.VIF are neither consulted nor modified in this case.

42.18 INTEL SGX INTERACTION WITH PROTECTION KEYS

SGX interactions with PKRU are as follows:

- CPUID.(EAX=12H, ECX=1):ECX.PKRU indicates whether SECS.ATTRIBUTES.XFRM.PKRU can be set. If SECS.ATTRIBUTES.XFRM.PKRU is set, then PKRU is saved and cleared as part of AEX and is restored as part of ERESUME. If CR4.PKE is set, an enclave can execute RDPKRU and WRKRU independent of whetherSECS.ATTRIBUTES.XFRM.PKRU is set.

SGX interactions with domain permission checks are as follows:

1) If CR4.PKE is not set, then legacy and SGX permission checks are not effected.

2) If CR4.PKE is set, then domain permission checks are applied to all non-enclave access and enclave accesses to user pages in addition to legacy and SGX permission checks at a higher priority than SGX permission checks

Implicit accesses aren't subject to domain permission checks.

CHAPTER 43
ENCLAVE CODE DEBUG AND PROFILING

Intel® SGX is architected to provide protection for production enclaves and permit enclave code developers to use an SGX-aware debugger to effectively debug a non-production enclave (debug enclave). Intel SGX also allows a non-SGX-aware debugger to debug non-enclave portions of the application without getting confused by enclave instructions.

43.1 CONFIGURATION AND CONTROLS

43.1.1 Debug Enclave vs. Production Enclave

The SECS of each enclave provides a bit, SECS.ATTRIBUTES.DEBUG, indicating whether the enclave is a debug enclave (if set) or a production enclave (if 0). If this bit is set, software outside the enclave can use EDBGRD/EDBGWR to access the EPC memory of the enclave. The value of DEBUG is not included in the measurement of the enclave and therefore doesn't require a special SIGSTRUCT to be generated for this matter.

The ATTRIBUTES field in the SECS is reported in the enclave's attestation, and is included in the key derivation for the enclave secrets that were protected by the enclave using Intel SGX keys when it ran as a production enclave will not be accessible by the debug enclave. A debugger needs to be aware that special debug content might be required for a debug enclave to run in a meaningful way.

EPC memory belonging to a debug enclave can be accessed via the EDBGRD/EDBGWR leaf functions (see Section 41.4), while that belonging to a non-debug enclave cannot be accessed by these leaf functions.

43.1.2 Tool-chain Opt-in

The TCS.FLAGS.DBGOPTIN bit controls interactions of certain debug and profiling features with enclaves, including code/data breakpoints, TF, RF, monitor trap flag, BTF, LBRs, BTM, BTS, and performance monitoring. This bit is forced to zero when EPC pages are added via EADD. A debugger can set this bit via EDBGWR to the TCS of a debug enclave.

An enclave entry through a TCS with the TCS.FLAGS.DBGOPTIN set to 0 is called an **opt-out entry**. Conversely, an enclave entry through a TCS with TCS.FLAGS.DBGOPTIN set to 1 is called an **opt-in entry**.

43.2 SINGLE STEP DEBUG

43.2.1 Single Stepping ENCLS Instruction Leafs

If the RFLAGS.TF bit is set at the beginning of ENCLS, then a single-step debug exception is pending on the instruction boundary immediately after the ENCLS instruction. Additionally, if the instruction is invoked from a VMX guest, and if the monitor trap flag is asserted at the time of the time of invocation, then an MTF VM exit is pending on the instruction boundary immediately after the instruction.

43.2.2 Single Stepping ENCLU Instruction Leafs

The interactions of the unprivileged Intel SGX instruction ENCLU are leaf dependent.

An enclave entry via EENTER/ERESUME leaf functions of the ENCLU, in certain cases, may clear the RFLAGS.TF bit, and suppress the monitor trap flag. In such situations, an exit from the enclave, either via the EEXIT leaf function or via an AEX restores the RFLAGS.TF bit and effectiveness of the monitor trap flag. The details of this

clearing/suppression and the exact pending of single stepping events across EENTER/ERESUME/EEXIT/AEX are covered in detail in Section 43.2.3.

If the RFLAGS.TF bit is set at the beginning of EREPORT or EGETKEY leafs, then a single-step debug exception is pending on the instruction boundary immediately after the ENCLU instruction. Additionally, if the instruction is invoked from a VMX guest, and if the monitor trap flag is asserted at the time of invocation, and if the monitor trap flag is not suppressed by the preceding enclave entry, then an MTF VM exit is pending on the instruction boundary immediately after the instruction.

Consistent with the IA32 and Intel® 64 architectures, a pending MTF VM exit takes priority over a pending debug exception. Additionally, if an SMI, an INIT, or an #MC is received on the same instruction boundary, then that event takes priority over both the pending MTF VM exit and the pending debug exception. In such a situation, the pending MTF VM exit and/or pending debug exception are handled in a manner consistent with the IA32 and Intel 64 architectures.

If the instruction under consideration results in a fault, then the control flow goes to the fault handler, and no single-step debug exception is asserted. In such a situation, if the instruction is executed from a VMX guest, and if the VMM has asserted the monitor trap flag, then an MTF VM exit is pending after the delivery of the fault through the IDT (i.e., before the first instruction of the OS handler). If a VM exit occurs before reaching that boundary, then the MTF VM exit is lost.

43.2.3 Single-stepping Enclave Entry with Opt-out Entry

43.2.3.1 Single Stepping without AEX

Figure 43-1 shows the most common case for single-stepping after an opt-out entry.

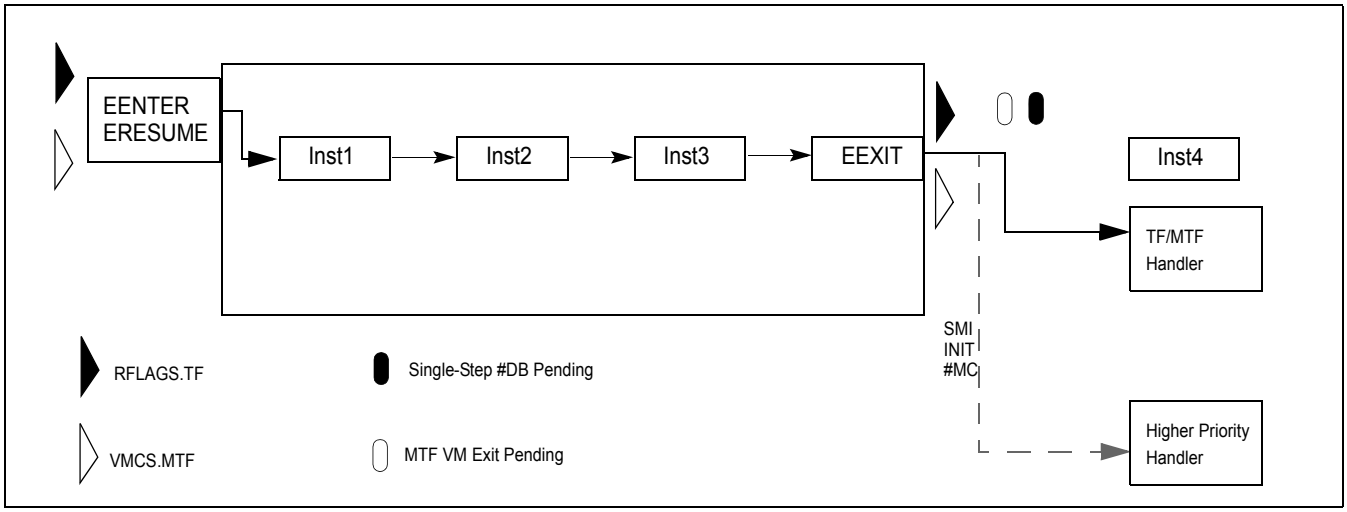

Figure 43-1. Single Stepping with Opt-out Entry - No AEX

In this scenario, if the RFLAGS.TF bit is set at the time of the enclave entry, then a single step debug exception is pending on the instruction boundary after EEXIT. Additionally, if the enclave is executing in a VMX guest, and if the monitor trap flag is asserted at the time of the enclave entry, then an MTF VM exit is pending on the instruction boundary after EEXIT.

The value of the RFLAGS.TF bit at the end of EEXIT is same as the value of RFLAGS.TF at the time of the enclave entry. Similarly, if the enclave is executing inside a VMX guest, then the value of the monitor trap flag after EEXIT is same as the value of that control at the time of the enclave entry.

Consistent with the IA32 and Intel 64 architectures, MTF VM exit, if pending, takes priority over a pending debug exception. If an SMI, an INIT, or an MC# is received on the same instruction boundary, then that event takes priority over both the pending MTF VM exit and the pending debug exception. In such a situation, the pending MTF

VM exit and/or pending debug exception are handled in a manner consistent with the IA32 and Intel 64 architecture.

43.2.3.2 Single Step Preempted by AEX due to Non-SMI Event

Figure 43-2 shows the interaction of single stepping with AEX due to a non-SMI event after an opt-out entry.

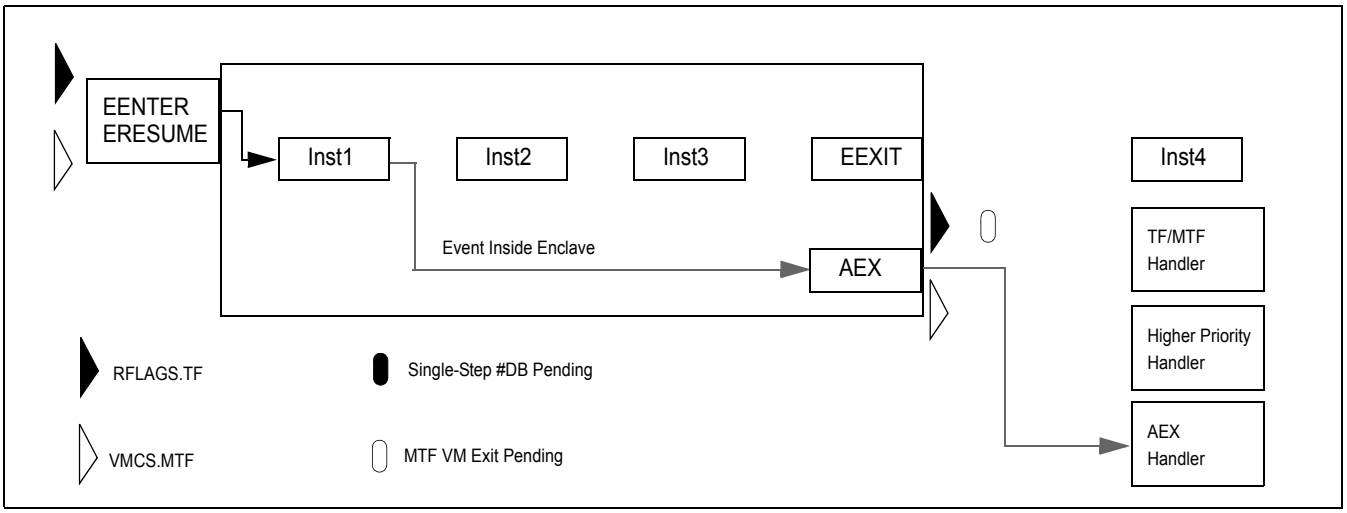

Figure 43-2. Single Stepping with Opt-out Entry -AEX Due to Non-SMI Event Before Single-Step Boundary

In this scenario, if the enclave is executing in a VMX guest, and if the monitor trap flag is asserted at the time of the enclave entry, then an MTF VM exit is pending on the instruction boundary after the delivery of the AEX. Consistent with the IA32 and Intel 64 architectures, if another VM exit happens before reaching that instruction boundary, the MTF VM exit is lost.

The value of the RFLAGS.TF bit at the end of AEX is same as the value of RFLAGS.TF at the time of the enclave entry. Also, if the enclave is executing inside a VMX guest, then the value of the monitor trap flag after AEX is the same as the value of that control at the time of the enclave entry.

43.2.4 RFLAGS.TF Treatment on AEX

When an opt-in enclave takes an AEX, RFLAGS.TF passes unmodified into synthetic state, and is saved as RFLAGS.TF=0 in the GPR portion of the SSA. For opt-out entry, the external value of TF is saved in CR_SAVE_TF, and TF is then cleared. For more detail see EENTER and ERESUME in Chapter 5.

43.2.5 Restriction on Setting of TF after an Opt-out Entry

From an opt-out EENTER or ERESUME until the next enclave exit, enclave is not allowed to set RFLAGS.TF. In such a situation, the POPF instruction forces RFLAGS.TF to 0 if the enclave was entered through TCS with DBGOPTIN=0.

43.2.6 Trampoline Code Considerations

Any AEX from the enclave which results in the RFLAGS.TF =1 on the reporting stack will result in a single-step #DB after the first instruction of the trampoline code if the trampoline is entered using the IRET instruction.

43.3 CODE AND DATA BREAKPOINTS

43.3.1 Breakpoint Suppression

On an opt-out entry into an enclave, all code and data breakpoints that overlap with the ELRANGE are suppressed. On any entry (either opt-in or opt-out) into an enclave, all code breakpoints that do not overlap with ELRANGE are also suppressed.

43.3.2 Breakpoint Match Reporting during Enclave Execution

The processor does not report any new matches on debug breakpoints that are suppressed on enclave entry. However, the processor does not clear any bits in DR6 that were already set at the time of the enclave entry.

Intel SGX architecture specifically forbids reporting of silent matches on any debug breakpoints that overlap with ELRANGE after an opt-out entry.

43.3.3 Reporting of Code Breakpoint on Next Instruction on a Debug Trap

If execution in an enclave encounters a single-step trap or an enabled data breakpoint, the logical processor performs an AEX. Following the AEX, the logical processor checks the new instruction pointer (the AEP address) against any code breakpoints programmed in DR0-DR3. Any matches are reported to software.

If execution in an enclave encounters an enabled code breakpoint, the logical processor checks the current instruction pointer (within the enclave) against any code breakpoints programmed in DR0-DR3. This checking for code breakpoints occurs before the AEX, the Intel SGX breakpoint-suppression architecture applies. Following this, the logical processor performs an AEX, after which any breakpoints matched earlier are reported to software.

43.3.4 RFLAGS.RF Treatment on AEX

RF is always set to 0 in synthetic state. This is because ERESUME after AEX is a new execution attempt.

RF value saved on SSA is the same as what would have been saved on stack in the non-SGX case. AEXs due to interrupts, traps, and code breakpoints save RF unmodified into SSA, while AEXs due to other faults save RF as 1 in the SSA.

43.3.5 Breakpoint Matching in Intel® SGX Instruction Flows

None of the implicit accesses made by Intel SGX instructions to EPC regions generate data breakpoints. Explicit accesses made by ENCLS[ECREATE], ENCLS[EADD], ENCLS[EEXTEND], ENCLS[EINIT], ENCLS[EREMOVE], ENCLS[ETRACK], ENCLS[EBLOCK], ENCLS[EPA], ENCLS[EWB], ENCLS[ELD], ENCLS[EDBGRD], ENCLS[EDBGWR], ENCLU[EENTER], and ENCLU[ERESUME] to the EPC parameters do not fire any data breakpoints.

Explicit accesses made by the remaining Intel SGX instructions (ENCLU[EGETKEY] and ENCLU[EREPORT]), trigger precise data breakpoints for their EPC operands. It should also be noted that all Intel SGX instructions trigger precise data breakpoints for their non-EPC operands.

After an opt-out entry, ENCLU[EGETKEY] and ENCLU[EREPORT] do not fire any of the data breakpoints that were suppressed as a part of the enclave entry.

43.4 INT3 CONSIDERATION

43.4.1 Behavior of INT3 inside an Enclave

Inside an enclave, INT3 delivers a fault-class exception. However, the vector delivered as a result of executing the instruction depends on the manner in which the enclave was entered. Following opt-out entry, the instruction delivers #UD. Following opt-in entry, INT3 delivers #BP.

Since the event is a fault-class exception, the delivery flow of the exception does not check CPL against the DPL in the IDT gate. (Normally, delivery of INT3 generates a #GP if CPL is greater than the DPL field in IDT gate 3.) Additionally, the RIP saved in the SSA is always that of the INT3 instruction. The RIP saved on the stack/VMCS is that of the trampoline code as specified by the AEX architecture.

If execution of INT3 in an enclave causes a VM exit, the event type in the VM-exit interruption information field indicates a hardware exception (type 3; not a software exception with type 6) and the VM-exit instruction length field is saved as zero.

43.4.2 Debugger Considerations

The INT3 is always fault-like inside an enclave. Consequently, the debugger must not decrement SSA.RIP for #BP coming from an enclave. INT3 will result in #UD, if the debugger is not attached to the enclave.

43.4.3 VMM Considerations

As described above, INT3 executed by enclave delivers #BP with "interruption type" of 3. This behavior will not cause any problems for VMMs that obtain VM-entry interruption information from appropriate VMCS field (as recommended in *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3C*), and those VMMs will continue to work seamlessly.

VMMs that fabricate the VM-entry interruption information based on the interruption vector need additional enabling. Specifically, such VMMs should be modified to use injection type of 3 (instead of 6) when they see interruption vector 3 along with the VMCS "Enclave Interruption" bit set.

43.5 BRANCH TRACING

43.5.1 BTF Treatment

Any single-step traps pending after EENTER trigger BTF exception, as EENTER is considered a branch instruction. Additionally, any single-step traps pending after EEXIT trigger BTF exception, as EEXIT is also considered a branch instruction. ERESUME does not trigger BTF traps. An AEX does not trigger BTF or TF traps.

43.5.2 LBR Treatment

43.5.2.1 LBR Stack on Opt-in Entry

An opt-in enclave entry does not change the behavior of IA32_DEBUGCTL.LBR bit. Both enclave entry and enclave exit push a record on LBR stack. EENTER/ERESUME with TCS.FLAGS.DBGOPTIN=1, inserts a new LBR record on the LBR stack. The MSR_LASTBRANCH_n_FROM_IP of this record holds linear address of the EENTER/ERESUME instruction, while MSR_LASTBRANCH_n_TO_IP of this record holds linear address of EENTER/ERESUME destination.

On EEXIT a new LBR record is pushed on the LBR stack. The MSR_LASTBRANCH_n_FROM_IP of this record holds linear address of the EEXIT instruction, while MSR_LASTBRANCH_n_TO_IP of this record holds the linear address of EEXIT destination.

On AEX a new LBR record is pushed on the LBR stack. The MSR_LASTBRANCH_n_FROM_IP of this record holds RIP saved in the SSA, while MSR_LASTBRANCH_n_TO_IP of this record holds RIP of the linear address of the AEP.

Additionally, for every branch inside the enclave, one record each is pushed on LBR stack.

Figure 43-3 shows an example of LBR stack manipulation after an opt-in entry. Every arrow in this picture indicates a branch record pushed on the LBR stack. The "From IP" of the branch record contains the linear address of the instruction located at the start of the arrow, while the "To IP" of the branch record contains the linear address of the instruction at the end of the arrow.

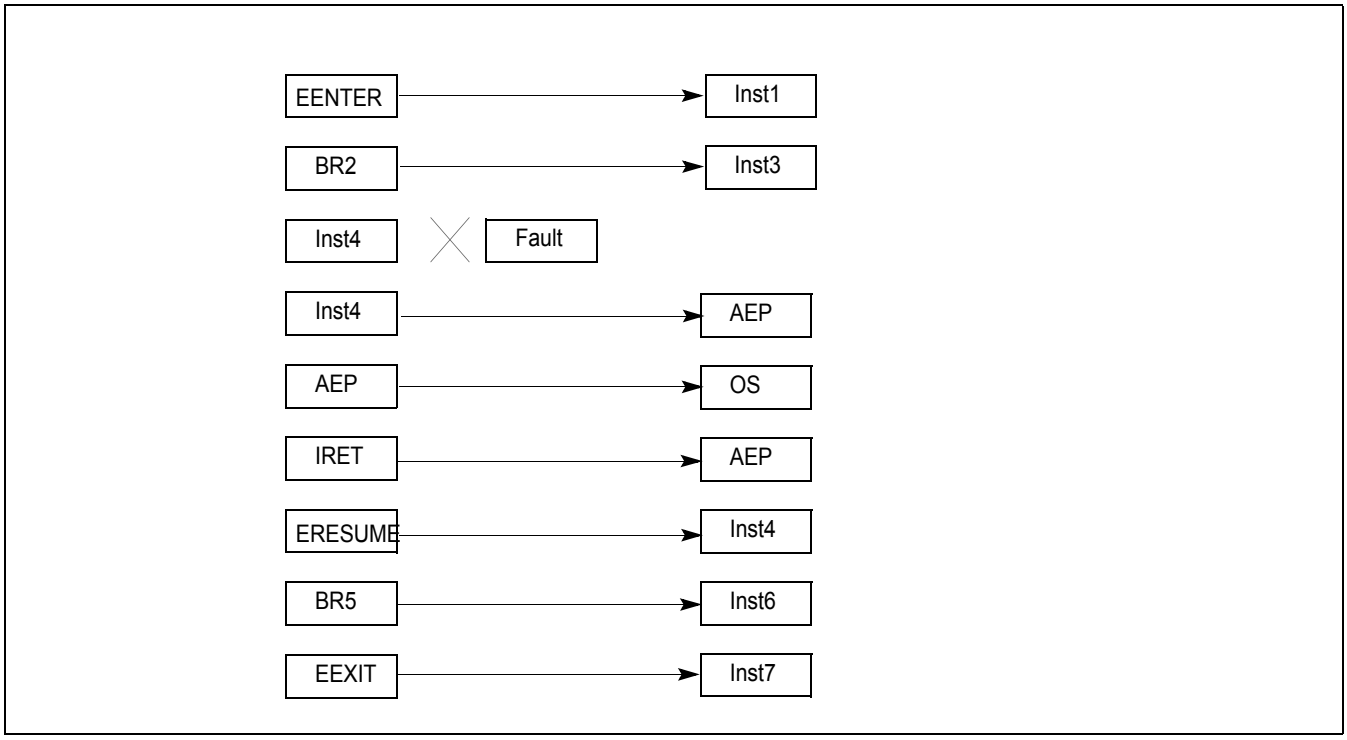

Figure 43-3. LBR Stack Interaction with Opt-in Entry

43.5.2.2 LBR Stack on Opt-out Entry

An opt-out entry into an enclave suppresses IA32_DEBUGCTL.LBR bit, and enclave exit after an opt-out entry un-suppresses the IA32_DEBUGCTL.LBR bit.

Opt-out entry into an enclave does not push any record on LBR stack.

If IA32_DEBUGCTL.LBR is set at the time of enclave entry, then EEXIT following such an enclave entry pushes one record on LBR stack. The MSR_LASTBRANCH_n_FROM_IP of such record holds the linear address of the instruction that took the logical processor into the enclave, while the MSR_LASTBRANCH_n_TO_IP of such record holds linear address of the destination of EEXIT. Additionally, if IA32_DEBUGCTL.LBR is set at the time of enclave entry, then an AEX after such an entry pushes one record on LBR stack, before pushing record for the event causing the AEX. The MSR_LASTBRANCH_n_FROM_IP of the new record holds linear address of the instruction that took the LP into the enclave, while MSR_LASTBRANCH_n_TO_IP of the new record holds linear address of the AEP. If the event causing AEX pushes a record on LBR stack, then the MSR_LASTBRANCH_n_FROM_IP for that record holds linear address of the AEP.

Figure 43-4 shows an example of LBR stack manipulation after an opt-out entry. Every arrow in this picture indicates a branch record pushed on the LBR stack. The "From IP" of the branch record contains the linear address of the instruction located at the start of the arrow, while the "To IP" of the branch record contains the linear address of the instruction at the end of the arrow.

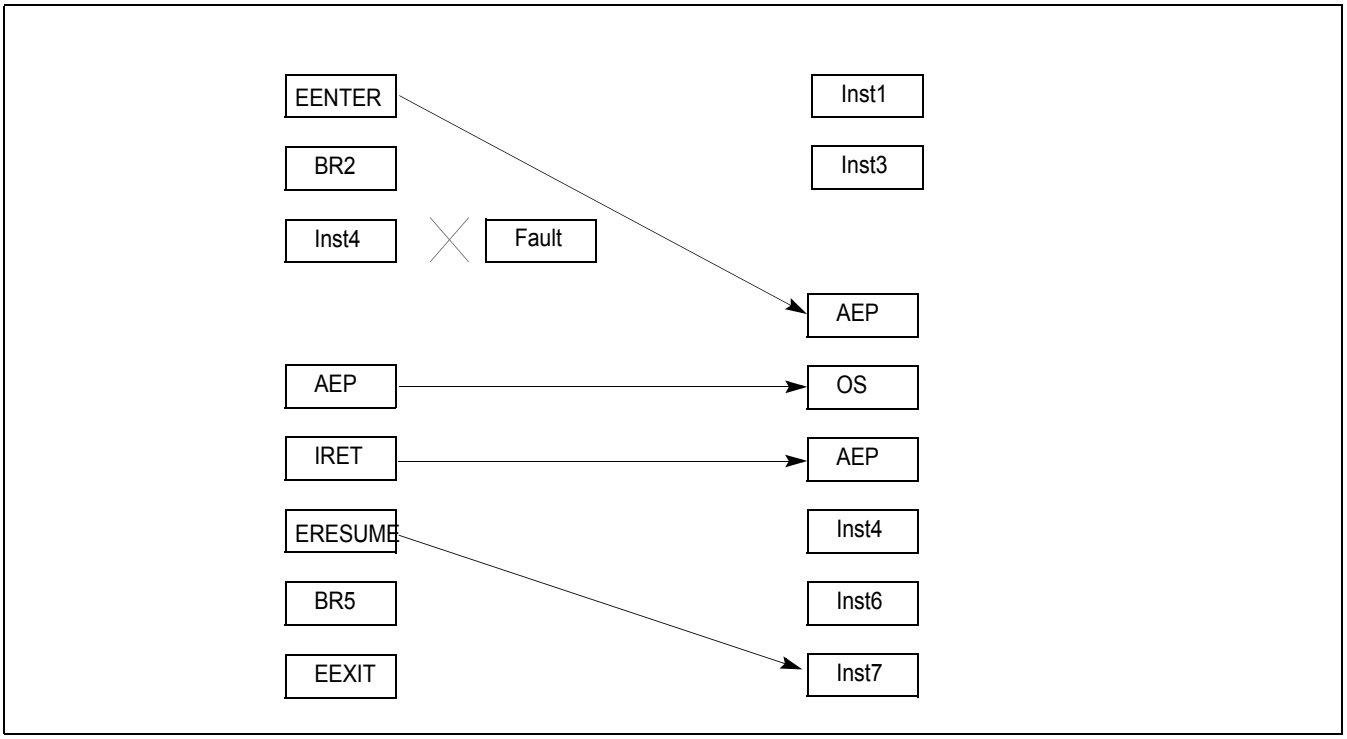

Figure 43-4. LBR Stack Interaction with Opt-out Entry

43.5.2.3 Mispredict Bit, Record Type, and Filtering

All branch records resulting from Intel SGX instructions/AEXs are reported as predicted branches, and consequently, bit 63 of MSR_LASTBRANCH_n_FROM_IP for such records is set. Branch records due to these Intel SGX operations are always non-HLE/non-RTM records.

For LBR filtering, EENTER, ERESUME, EEXIT, and AEX are considered to be far branches. Consequently, bit 8 in MSR_LBR_SELECT controls filtering of the new records introduced by Intel SGX.

43.6 INTERACTION WITH PERFORMANCE MONITORING

43.6.1 IA32_PERF_GLOBAL_STATUS Enhancement

On processors supporting Intel SGX, the IA32_PERF_GLOBAL_STATUS MSR provides a bit indicator, known as "Anti Side-channel Interference" (ASCI) at bit position 60. If this bit is 0, the performance monitoring data in various performance monitoring counters are accumulated normally as defined by relevant architectural/microarchitectural conditions associated with the eventing logic. If the ASCI bit is set, the contents in various performance monitoring counters can be affected by the direct or indirect consequence of Intel SGX protection of enclave code executing in the processor.

43.6.2 Performance Monitoring with Opt-in Entry

An opt-in enclave entry allow performance monitoring eventing logic to observe the contribution of enclave code executing in the processor. Thus the contents of performance monitoring counters does not distinguish between contribution originating from enclave code or otherwise. All counters, events, precise events, etc. continue to work as defined in the IA32/Intel 64 Software Developer Manual. Consequently, bit 60 of IA32_PERF_GLOBAL_STATUS MSR is always cleared.

43.6.3 Performance Monitoring with Opt-out Entry

In general, performance monitoring activities are suppressed when entering an opt-out enclave. This applies to all thread-specific, configured performance monitoring, except for the cycle-counting fixed counter, IA32_FIXED_CTR1 and IA32_FIXED_CTR2. Upon entering an opt-out enclave, IA32_FIXED_CTR0, IA32_PMCx will stop accumulating counts. Additionally, if PEBS is configured to capture PEBS record for this thread, PEBS record generation will also be suppressed.

Performance monitoring on the sibling thread may also be affected. Any one of IA32_FIXED_CTRx or IA32_PMCx on the sibling thread configured to monitor thread-specific eventing logic with AnyThread =1 is demoted to count only MyThread while an opt-out enclave is executing on the other thread.

43.6.4 Enclave Exit and Performance Monitoring

When a logical processor exits an enclave, either via ENCLU[EEXIT] or via AEX, all performance monitoring activity (including PEBS) on that logical processor that was suppressed is unsuppressed.

Any counters that were demoted from AnyThread to MyThread on the sibling thread are promoted back to AnyThread.

43.6.5 PEBS Record Generation on Intel® SGX Instructions

All leaf functions of the ENCLS instruction report "Eventing RIP" of the ENCLS instruction if a PEBS record is generated at the end of the instruction execution. Additionally, the EGETKEY and EREPORT leaf functions of the ENCLU instruction report "Eventing RIP" of the ENCLU instruction if a PEBS record is generated at the end of the instruction execution.

The behavior of EENTER and ERESUME leaf functions of the ENCLU instruction depends on whether these leaf functions are performing an opt-in entry or an opt-out entry. If these leaf functions are performing an opt-in entry report "Eventing RIP" of the ENCLU instruction if a PEBS record is generated at the end of the instruction execution. On the other hand, if these leaf functions are performing an opt-out entry, then these leaf functions result in PEBS being suppressed, and no PEBS record is generated at the end of these instructions.

The behavior of the EEXIT leaf function is as follows. A PEBS record is generated if there is a PEBS event pending at the end of EEXIT (due to a counter overflowing during enclave execution or during EEXIT execution). This PEBS record contains the architectural state of the logical processor at the end of EEXIT. If the enclave was entered via an opt-in entry, then this record reports the "Eventing RIP" as the linear address of the ENCLU[EEXIT] instruction (which is inside ELRANGE of the enclave just exited). If the enclave was entered via an opt-out entry, then the record reports the "Eventing RIP" as the linear address of the ENCLU[EENTER/ERESUME] instruction that performed the last enclave entry.

A PEBS record is generated immediately after the AEX if there is a PEBS event pending at the end of AEX (due to a counter overflowing during enclave execution or during AEX execution). This PEBS record contains the synthetic state of the logical processor that is established at the end of AEX. For opt-in entry, this record has the EVENTING_RIP set to the eventing LIP in the enclave. For opt-out entry, the record has the EVENTING_RIP set to EENTER/ERESUME LIP.

If the enclave was entered via an opt-in entry, then this record reports the "Eventing RIP" as the linear address in the SSA of the enclave (a.k.a., the "Eventing LIP" inside the enclave). If the enclave was entered via an opt-out entry, then the record reports the "Eventing RIP" as the linear address of the ENCLU[EENTER/ERESUME] instruction that performed the last enclave entry.

It should be noted that a second PEBS event may be pended during the Enclave Exiting Event (EEE). If the PEBS event is taken at the end of the EEE then the "Eventing RIP" in this second PEBS record is the linear address of the AEP.

43.6.6 Exception-Handling on PEBS/BTS Loads/Stores after AEX

The OS/VMM is expected to pin the DS area in virtual memory. If the OS does not pin this area in memory, loads/stores to the PEBS or BTS buffer may incur faults (or other events such as APIC-access VM exit). Usually, such events are reported to the OS/VMM immediately, and generation of the PEBS/BTS record is skipped.

However, any events that are detected during PEBS/BTS record generation cannot be reported immediately to the OS/VMM, as an event window is not open at the end of AEX. Consequently, fault-like events such as page faults, EPT faults, EPT mis-configuration, and accesses to APIC-access page detected on stores to the PEBS/BTS buffer are not reported, and generation of the PEBS and/or BTS record is aborted (this may leave the buffers in a state where they have partial PEBS or BTS records), while trap-like events (such as debug traps) are pended until the next instruction boundary, where they are handled according to the architecturally defined priority. The processor continues the handling of the Enclave Exiting Event (SMI, NMI, interrupt, exception delivery, VM exit, etc.) after aborting the PEBS/BTS record generation.

43.6.6.1 Other Interactions with Performance Monitoring

For opt-in entry, EENTER, ERESUME, EEXIT, and AEX are all treated as predicted branches, and any counters that are counting such branches are incremented by 1 as a part of execution of these instructions. All of these flows are also counted as instructions, and any counters configured appropriately are incremented by 1.

For opt-out entry, execution inside an enclave is treated as a single predicted branch, and all branch-counting performance monitoring counters are incremented accordingly. Additionally, such execution is also counted as a single instruction, and all performance monitoring counters counting instructions are incremented accordingly.

Enclave entry does not affect any performance monitoring counters shared between cores.

EENTER, ERESUME, EEXIT and AEX are classified as far branches.

APPENDIX A
VMX CAPABILITY REPORTING FACILITY

The ability of a processor to support VMX operation and related instructions is indicated by CPUID.1:ECX.VMX[bit 5] = 1. A value 1 in this bit indicates support for VMX features.

Support for specific features detailed in Chapter 26 and other VMX chapters is determined by reading values from a set of capability MSRs. These MSRs are indexed starting at MSR address 480H. VMX capability MSRs are read-only; an attempt to write them (with WRMSR) produces a general-protection exception (#GP(0)). They do not exist on processors that do not support VMX operation; an attempt to read them (with RDMSR) on such processors produces a general-protection exception (#GP(0)).

A.1 BASIC VMX INFORMATION

The IA32_VMX_BASIC MSR (index 480H) consists of the following fields:

- Bits 30:0 contain the 31-bit VMCS revision identifier used by the processor. Processors that use the same VMCS revision identifier use the same size for VMCS regions (see subsequent item on bits 44:32).[1]
- Bit 31 is always 0.
- Bits 44:32 report the number of bytes that software should allocate for the VMXON region and any VMCS region. It is a value greater than 0 and at most 4096 (bit 44 is set if and only if bits 43:32 are clear).
- Bit 48 indicates the width of the physical addresses that may be used for the VMXON region, each VMCS, and data structures referenced by pointers in a VMCS (I/O bitmaps, virtual-APIC page, MSR areas for VMX transitions). If the bit is 0, these addresses are limited to the processor's physical-address width.[2] If the bit is 1, these addresses are limited to 32 bits. This bit is always 0 for processors that support Intel 64 architecture.
- If bit 49 is read as 1, the logical processor supports the dual-monitor treatment of system-management interrupts and system-management mode. See Section 34.15 for details of this treatment.
- Bits 53:50 report the memory type that should be used for the VMCS, for data structures referenced by pointers in the VMCS (I/O bitmaps, virtual-APIC page, MSR areas for VMX transitions), and for the MSEG header. If software needs to access these data structures (e.g., to modify the contents of the MSR bitmaps), it can configure the paging structures to map them into the linear-address space. If it does so, it should establish mappings that use the memory type reported bits 53:50 in this MSR.[3]

  As of this writing, all processors that support VMX operation indicate the write-back type. The values used are given in Table A-1.

Table A-1. Memory Types Recommended for VMCS and Related Data Structures

Value(s)	Field
0	Uncacheable (UC)
1–5	Not used
6	Write Back (WB)
7–15	Not used

1. Earlier versions of this manual specified that the VMCS revision identifier was a 32-bit field in bits 31:0 of this MSR. For all processors produced prior to this change, bit 31 of this MSR was read as 0.
2. On processors that support Intel 64 architecture, the pointer must not set bits beyond the processor's physical address width.
3. Alternatively, software may map any of these regions or structures with the UC memory type. (This may be necessary for the MSEG header.) Doing so is discouraged unless necessary as it will cause the performance of software accesses to those structures to suffer.

If software needs to access these data structures (e.g., to modify the contents of the MSR bitmaps), it can configure the paging structures to map them into the linear-address space. If it does so, it should establish mappings that use the memory type reported in this MSR.[1]

- If bit 54 is read as 1, the logical processor reports information in the VM-exit instruction-information field on VM exits due to execution of the INS and OUTS instructions. This reporting is done only if this bit is read as 1.
- Bit 55 is read as 1 if any VMX controls that default to 1 may be cleared to 0. See Appendix A.2 for details. It also reports support for the VMX capability MSRs IA32_VMX_TRUE_PINBASED_CTLS, IA32_VMX_TRUE_PROCBASED_CTLS, IA32_VMX_TRUE_EXIT_CTLS, and IA32_VMX_TRUE_ENTRY_CTLS. See Appendix A.3.1, Appendix A.3.2, Appendix A.4, and Appendix A.5 for details.
- The values of bits 47:45 and bits 63:56 are reserved and are read as 0.

A.2 RESERVED CONTROLS AND DEFAULT SETTINGS

As noted in Chapter 26, "VM Entries", certain VMX controls are reserved and must be set to a specific value (0 or 1) determined by the processor. The specific value to which a reserved control must be set is its **default setting**. Software can discover the default setting of a reserved control by consulting the appropriate VMX capability MSR (see Appendix A.3 through Appendix A.5).

Future processors may define new functionality for one or more reserved controls. Such processors would allow each newly defined control to be set either to 0 or to 1. Software that does not desire a control's new functionality should set the control to its default setting. For that reason, it is useful for software to know the default settings of the reserved controls.

Default settings partition the various controls into the following classes:

- **Always-flexible**. These have never been reserved.
- **Default0**. These are (or have been) reserved with a default setting of 0.
- **Default1**. They are (or have been) reserved with a default setting of 1.

As noted in Appendix A.1, a logical processor uses bit 55 of the IA32_VMX_BASIC MSR to indicate whether any of the default1 controls may be 0:

- If bit 55 of the IA32_VMX_BASIC MSR is read as 0, all the default1 controls are reserved and must be 1. VM entry will fail if any of these controls are 0 (see Section 26.2.1).
- If bit 55 of the IA32_VMX_BASIC MSR is read as 1, not all the default1 controls are reserved, and some (but not necessarily all) may be 0. The CPU supports four (4) new VMX capability MSRs: IA32_VMX_TRUE_PINBASED_CTLS, IA32_VMX_TRUE_PROCBASED_CTLS, IA32_VMX_TRUE_EXIT_CTLS, and IA32_VMX_TRUE_ENTRY_CTLS. See Appendix A.3 through Appendix A.5 for details. (These MSRs are not supported if bit 55 of the IA32_VMX_BASIC MSR is read as 0.)

See Section 31.5.1 for recommended software algorithms for proper capability detection of the default1 controls.

A.3 VM-EXECUTION CONTROLS

There are separate capability MSRs for the pin-based VM-execution controls, the primary processor-based VM-execution controls, and the secondary processor-based VM-execution controls. These are described in Appendix A.3.1, Appendix A.3.2, and Appendix A.3.3, respectively.

1. Alternatively, software may map any of these regions or structures with the UC memory type. (This may be necessary for the MSEG header.) Doing so is discouraged unless necessary as it will cause the performance of software accesses to those structures to suffer. The processor will continue to use the memory type reported in the VMX capability MSR IA32_VMX_BASIC with the exceptions noted.

A.3.1 Pin-Based VM-Execution Controls

The IA32_VMX_PINBASED_CTLS MSR (index 481H) reports on the allowed settings of **most** of the pin-based VM-execution controls (see Section 24.6.1):

- Bits 31:0 indicate the **allowed 0-settings** of these controls. VM entry allows control X (bit X of the pin-based VM-execution controls) to be 0 if bit X in the MSR is cleared to 0; if bit X in the MSR is set to 1, VM entry fails if control X is 0.

  Exceptions are made for the pin-based VM-execution controls in the default1 class (see Appendix A.2). These are bits 1, 2, and 4; the corresponding bits of the IA32_VMX_PINBASED_CTLS MSR are always read as 1. The treatment of these controls by VM entry is determined by bit 55 in the IA32_VMX_BASIC MSR:

  — If bit 55 in the IA32_VMX_BASIC MSR is read as 0, VM entry fails if any pin-based VM-execution control in the default1 class is 0.

  — If bit 55 in the IA32_VMX_BASIC MSR is read as 1, the IA32_VMX_TRUE_PINBASED_CTLS MSR (see below) reports which of the pin-based VM-execution controls in the default1 class can be 0 on VM entry.

- Bits 63:32 indicate the **allowed 1-settings** of these controls. VM entry allows control X to be 1 if bit 32+X in the MSR is set to 1; if bit 32+X in the MSR is cleared to 0, VM entry fails if control X is 1.

If bit 55 in the IA32_VMX_BASIC MSR is read as 1, the IA32_VMX_TRUE_PINBASED_CTLS MSR (index 48DH) reports on the allowed settings of **all** of the pin-based VM-execution controls:

- Bits 31:0 indicate the allowed 0-settings of these controls. VM entry allows control X to be 0 if bit X in the MSR is cleared to 0; if bit X in the MSR is set to 1, VM entry fails if control X is 0. There are no exceptions.
- Bits 63:32 indicate the allowed 1-settings of these controls. VM entry allows control X to be 1 if bit 32+X in the MSR is set to 1; if bit 32+X in the MSR is cleared to 0, VM entry fails if control X is 1.

It is necessary for software to consult only one of the capability MSRs to determine the allowed settings of the pin-based VM-execution controls:

- If bit 55 in the IA32_VMX_BASIC MSR is read as 0, all information about the allowed settings of the pin-based VM-execution controls is contained in the IA32_VMX_PINBASED_CTLS MSR. (The IA32_VMX_TRUE_PINBASED_CTLS MSR is not supported.)
- If bit 55 in the IA32_VMX_BASIC MSR is read as 1, all information about the allowed settings of the pin-based VM-execution controls is contained in the IA32_VMX_TRUE_PINBASED_CTLS MSR. Assuming that software knows that the default1 class of pin-based VM-execution controls contains bits 1, 2, and 4, there is no need for software to consult the IA32_VMX_PINBASED_CTLS MSR.

A.3.2 Primary Processor-Based VM-Execution Controls

The IA32_VMX_PROCBASED_CTLS MSR (index 482H) reports on the allowed settings of **most** of the primary processor-based VM-execution controls (see Section 24.6.2):

- Bits 31:0 indicate the allowed 0-settings of these controls. VM entry allows control X (bit X of the primary processor-based VM-execution controls) to be 0 if bit X in the MSR is cleared to 0; if bit X in the MSR is set to 1, VM entry fails if control X is 0.

  Exceptions are made for the primary processor-based VM-execution controls in the default1 class (see Appendix A.2). These are bits 1, 4–6, 8, 13–16, and 26; the corresponding bits of the IA32_VMX_PROCBASED_CTLS MSR are always read as 1. The treatment of these controls by VM entry is determined by bit 55 in the IA32_VMX_BASIC MSR:

  — If bit 55 in the IA32_VMX_BASIC MSR is read as 0, VM entry fails if any of the primary processor-based VM-execution controls in the default1 class is 0.

  — If bit 55 in the IA32_VMX_BASIC MSR is read as 1, the IA32_VMX_TRUE_PROCBASED_CTLS MSR (see below) reports which of the primary processor-based VM-execution controls in the default1 class can be 0 on VM entry.

- Bits 63:32 indicate the allowed 1-settings of these controls. VM entry allows control X to be 1 if bit 32+X in the MSR is set to 1; if bit 32+X in the MSR is cleared to 0, VM entry fails if control X is 1.

If bit 55 in the IA32_VMX_BASIC MSR is read as 1, the IA32_VMX_TRUE_PROCBASED_CTLS MSR (index 48EH) reports on the allowed settings of **all** of the primary processor-based VM-execution controls:

- Bits 31:0 indicate the allowed 0-settings of these controls. VM entry allows control X to be 0 if bit X in the MSR is cleared to 0; if bit X in the MSR is set to 1, VM entry fails if control X is 0. There are no exceptions.
- Bits 63:32 indicate the allowed 1-settings of these controls. VM entry allows control X to be 1 if bit 32+X in the MSR is set to 1; if bit 32+X in the MSR is cleared to 0, VM entry fails if control X is 1.

It is necessary for software to consult only one of the capability MSRs to determine the allowed settings of the primary processor-based VM-execution controls:

- If bit 55 in the IA32_VMX_BASIC MSR is read as 0, all information about the allowed settings of the primary processor-based VM-execution controls is contained in the IA32_VMX_PROCBASED_CTLS MSR. (The IA32_VMX_TRUE_PROCBASED_CTLS MSR is not supported.)
- If bit 55 in the IA32_VMX_BASIC MSR is read as 1, all information about the allowed settings of the processor-based VM-execution controls is contained in the IA32_VMX_TRUE_PROCBASED_CTLS MSR. Assuming that software knows that the default1 class of processor-based VM-execution controls contains bits 1, 4–6, 8, 13–16, and 26, there is no need for software to consult the IA32_VMX_PROCBASED_CTLS MSR.

A.3.3 Secondary Processor-Based VM-Execution Controls

The IA32_VMX_PROCBASED_CTLS2 MSR (index 48BH) reports on the allowed settings of the secondary processor-based VM-execution controls (see Section 24.6.2). VM entries perform the following checks:

- Bits 31:0 indicate the allowed 0-settings of these controls. These bits are always 0. This fact indicates that VM entry allows each bit of the secondary processor-based VM-execution controls to be 0 (reserved bits must be 0)
- Bits 63:32 indicate the allowed 1-settings of these controls; the 1-setting is not allowed for any reserved bit. VM entry allows control X (bit X of the secondary processor-based VM-execution controls) to be 1 if bit 32+X in the MSR is set to 1; if bit 32+X in the MSR is cleared to 0, VM entry fails if control X and the "activate secondary controls" primary processor-based VM-execution control are both 1.

The IA32_VMX_PROCBASED_CTLS2 MSR exists only on processors that support the 1-setting of the "activate secondary controls" VM-execution control (only if bit 63 of the IA32_VMX_PROCBASED_CTLS MSR is 1).

A.4 VM-EXIT CONTROLS

The IA32_VMX_EXIT_CTLS MSR (index 483H) reports on the allowed settings of **most** of the VM-exit controls (see Section 24.7.1):

- Bits 31:0 indicate the allowed 0-settings of these controls. VM entry allows control X (bit X of the VM-exit controls) to be 0 if bit X in the MSR is cleared to 0; if bit X in the MSR is set to 1, VM entry fails if control X is 0.

  Exceptions are made for the VM-exit controls in the default1 class (see Appendix A.2). These are bits 0–8, 10, 11, 13, 14, 16, and 17; the corresponding bits of the IA32_VMX_EXIT_CTLS MSR are always read as 1. The treatment of these controls by VM entry is determined by bit 55 in the IA32_VMX_BASIC MSR:

  — If bit 55 in the IA32_VMX_BASIC MSR is read as 0, VM entry fails if any VM-exit control in the default1 class is 0.

  — If bit 55 in the IA32_VMX_BASIC MSR is read as 1, the IA32_VMX_TRUE_EXIT_CTLS MSR (see below) reports which of the VM-exit controls in the default1 class can be 0 on VM entry.
- Bits 63:32 indicate the allowed 1-settings of these controls. VM entry allows control 32+X to be 1 if bit X in the MSR is set to 1; if bit 32+X in the MSR is cleared to 0, VM entry fails if control X is 1.

If bit 55 in the IA32_VMX_BASIC MSR is read as 1, the IA32_VMX_TRUE_EXIT_CTLS MSR (index 48FH) reports on the allowed settings of **all** of the VM-exit controls:

- Bits 31:0 indicate the allowed 0-settings of these controls. VM entry allows control X to be 0 if bit X in the MSR is cleared to 0; if bit X in the MSR is set to 1, VM entry fails if control X is 0. There are no exceptions.

- Bits 63:32 indicate the allowed 1-settings of these controls. VM entry allows control X to be 1 if bit 32+X in the MSR is set to 1; if bit 32+X in the MSR is cleared to 0, VM entry fails if control X is 1.

It is necessary for software to consult only one of the capability MSRs to determine the allowed settings of the VM-exit controls:

- If bit 55 in the IA32_VMX_BASIC MSR is read as 0, all information about the allowed settings of the VM-exit controls is contained in the IA32_VMX_EXIT_CTLS MSR. (The IA32_VMX_TRUE_EXIT_CTLS MSR is not supported.)
- If bit 55 in the IA32_VMX_BASIC MSR is read as 1, all information about the allowed settings of the VM-exit controls is contained in the IA32_VMX_TRUE_EXIT_CTLS MSR. Assuming that software knows that the default1 class of VM-exit controls contains bits 0–8, 10, 11, 13, 14, 16, and 17, there is no need for software to consult the IA32_VMX_EXIT_CTLS MSR.

A.5 VM-ENTRY CONTROLS

The IA32_VMX_ENTRY_CTLS MSR (index 484H) reports on the allowed settings of **most** of the VM-entry controls (see Section 24.8.1):

- Bits 31:0 indicate the allowed 0-settings of these controls. VM entry allows control X (bit X of the VM-entry controls) to be 0 if bit X in the MSR is cleared to 0; if bit X in the MSR is set to 1, VM entry fails if control X is 0.

  Exceptions are made for the VM-entry controls in the default1 class (see Appendix A.2). These are bits 0–8 and 12; the corresponding bits of the IA32_VMX_ENTRY_CTLS MSR are always read as 1. The treatment of these controls by VM entry is determined by bit 55 in the IA32_VMX_BASIC MSR:

  — If bit 55 in the IA32_VMX_BASIC MSR is read as 0, VM entry fails if any VM-entry control in the default1 class is 0.

  — If bit 55 in the IA32_VMX_BASIC MSR is read as 1, the IA32_VMX_TRUE_ENTRY_CTLS MSR (see below) reports which of the VM-entry controls in the default1 class can be 0 on VM entry.
- Bits 63:32 indicate the allowed 1-settings of these controls. VM entry fails if bit X is 1 in the VM-entry controls and bit 32+X is 0 in this MSR.

If bit 55 in the IA32_VMX_BASIC MSR is read as 1, the IA32_VMX_TRUE_ENTRY_CTLS MSR (index 490H) reports on the allowed settings of **all** of the VM-entry controls:

- Bits 31:0 indicate the allowed 0-settings of these controls. VM entry allows control X to be 0 if bit X in the MSR is cleared to 0; if bit X in the MSR is set to 1, VM entry fails if control X is 0. There are no exceptions.
- Bits 63:32 indicate the allowed 1-settings of these controls. VM entry allows control 32+X to be 1 if bit X in the MSR is set to 1; if bit 32+X in the MSR is cleared to 0, VM entry fails if control X is 1.

It is necessary for software to consult only one of the capability MSRs to determine the allowed settings of the VM-entry controls:

- If bit 55 in the IA32_VMX_BASIC MSR is read as 0, all information about the allowed settings of the VM-entry controls is contained in the IA32_VMX_ENTRY_CTLS MSR. (The IA32_VMX_TRUE_ENTRY_CTLS MSR is not supported.)
- If bit 55 in the IA32_VMX_BASIC MSR is read as 1, all information about the allowed settings of the VM-entry controls is contained in the IA32_VMX_TRUE_ENTRY_CTLS MSR. Assuming that software knows that the default1 class of VM-entry controls contains bits 0–8 and 12, there is no need for software to consult the IA32_VMX_ENTRY_CTLS MSR.

A.6 MISCELLANEOUS DATA

The IA32_VMX_MISC MSR (index 485H) consists of the following fields:

- Bits 4:0 report a value X that specifies the relationship between the rate of the VMX-preemption timer and that of the timestamp counter (TSC). Specifically, the VMX-preemption timer (if it is active) counts down by 1 every time bit X in the TSC changes due to a TSC increment.

- If bit 5 is read as 1, VM exits store the value of IA32_EFER.LMA into the "IA-32e mode guest" VM-entry control; see Section 27.2 for more details. This bit is read as 1 on any logical processor that supports the 1-setting of the "unrestricted guest" VM-execution control.
- Bits 8:6 report, as a bitmap, the activity states supported by the implementation:
  - — Bit 6 reports (if set) the support for activity state 1 (HLT).
  - — Bit 7 reports (if set) the support for activity state 2 (shutdown).
  - — Bit 8 reports (if set) the support for activity state 3 (wait-for-SIPI).

  If an activity state is not supported, the implementation causes a VM entry to fail if it attempts to establish that activity state. All implementations support VM entry to activity state 0 (active).
- If bit 15 is read as 1, the RDMSR instruction can be used in system-management mode (SMM) to read the IA32_SMBASE MSR (MSR address 9EH). See Section 34.15.6.4.
- Bits 24:16 indicate the number of CR3-target values supported by the processor. This number is a value between 0 and 256, inclusive (bit 24 is set if and only if bits 23:16 are clear).
- Bits 27:25 is used to compute the recommended maximum number of MSRs that should appear in the VM-exit MSR-store list, the VM-exit MSR-load list, or the VM-entry MSR-load list. Specifically, if the value bits 27:25 of IA32_VMX_MISC is N, then 512 * (N + 1) is the recommended maximum number of MSRs to be included in each list. If the limit is exceeded, undefined processor behavior may result (including a machine check during the VMX transition).
- If bit 28 is read as 1, bit 2 of the IA32_SMM_MONITOR_CTL can be set to 1. VMXOFF unblocks SMIs unless IA32_SMM_MONITOR_CTL[bit 2] is 1 (see Section 34.14.4).
- If bit 29 is read as 1, software can use VMWRITE to write to any supported field in the VMCS; otherwise, VMWRITE cannot be used to modify VM-exit information fields.
- Bits 63:32 report the 32-bit MSEG revision identifier used by the processor.
- Bits 14:9 and bits 31:30 are reserved and are read as 0.

A.7 VMX-FIXED BITS IN CR0

The IA32_VMX_CR0_FIXED0 MSR (index 486H) and IA32_VMX_CR0_FIXED1 MSR (index 487H) indicate how bits in CR0 may be set in VMX operation. They report on bits in CR0 that are allowed to be 0 and to be 1, respectively, in VMX operation. If bit X is 1 in IA32_VMX_CR0_FIXED0, then that bit of CR0 is fixed to 1 in VMX operation. Similarly, if bit X is 0 in IA32_VMX_CR0_FIXED1, then that bit of CR0 is fixed to 0 in VMX operation. It is always the case that, if bit X is 1 in IA32_VMX_CR0_FIXED0, then that bit is also 1 in IA32_VMX_CR0_FIXED1; if bit X is 0 in IA32_VMX_CR0_FIXED1, then that bit is also 0 in IA32_VMX_CR0_FIXED0. Thus, each bit in CR0 is either fixed to 0 (with value 0 in both MSRs), fixed to 1 (1 in both MSRs), or flexible (0 in IA32_VMX_CR0_FIXED0 and 1 in IA32_VMX_CR0_FIXED1).

A.8 VMX-FIXED BITS IN CR4

The IA32_VMX_CR4_FIXED0 MSR (index 488H) and IA32_VMX_CR4_FIXED1 MSR (index 489H) indicate how bits in CR4 may be set in VMX operation. They report on bits in CR4 that are allowed to be 0 and 1, respectively, in VMX operation. If bit X is 1 in IA32_VMX_CR4_FIXED0, then that bit of CR4 is fixed to 1 in VMX operation. Similarly, if bit X is 0 in IA32_VMX_CR4_FIXED1, then that bit of CR4 is fixed to 0 in VMX operation. It is always the case that, if bit X is 1 in IA32_VMX_CR4_FIXED0, then that bit is also 1 in IA32_VMX_CR4_FIXED1; if bit X is 0 in IA32_VMX_CR4_FIXED1, then that bit is also 0 in IA32_VMX_CR4_FIXED0. Thus, each bit in CR4 is either fixed to 0 (with value 0 in both MSRs), fixed to 1 (1 in both MSRs), or flexible (0 in IA32_VMX_CR4_FIXED0 and 1 in IA32_VMX_CR4_FIXED1).

A.9 VMCS ENUMERATION

The IA32_VMX_VMCS_ENUM MSR (index 48AH) provides information to assist software in enumerating fields in the VMCS.

As noted in Section 24.11.2, each field in the VMCS is associated with a 32-bit encoding which is structured as follows:

- Bits 31:15 are reserved (must be 0).
- Bits 14:13 indicate the field's width.
- Bit 12 is reserved (must be 0).
- Bits 11:10 indicate the field's type.
- Bits 9:1 is an index field that distinguishes different fields with the same width and type.
- Bit 0 indicates access type.

IA32_VMX_VMCS_ENUM indicates to software the highest index value used in the encoding of any field supported by the processor:

- Bits 9:1 contain the highest index value used for any VMCS encoding.
- Bit 0 and bits 63:10 are reserved and are read as 0.

A.10 VPID AND EPT CAPABILITIES

The IA32_VMX_EPT_VPID_CAP MSR (index 48CH) reports information about the capabilities of the logical processor with regard to virtual-processor identifiers (VPIDs, Section 28.1) and extended page tables (EPT, Section 28.2):

- If bit 0 is read as 1, the logical processor allows software to configure EPT paging-structure entries in which bits 2:0 have value 100b (indicating an execute-only translation).
- Bit 6 indicates support for a page-walk length of 4.
- If bit 8 is read as 1, the logical processor allows software to configure the EPT paging-structure memory type to be uncacheable (UC); see Section 24.6.11.
- If bit 14 is read as 1, the logical processor allows software to configure the EPT paging-structure memory type to be write-back (WB).
- If bit 16 is read as 1, the logical processor allows software to configure a EPT PDE to map a 2-Mbyte page (by setting bit 7 in the EPT PDE).
- If bit 17 is read as 1, the logical processor allows software to configure a EPT PDPTE to map a 1-Gbyte page (by setting bit 7 in the EPT PDPTE).
- Support for the INVEPT instruction (see Chapter 30 and Section 28.3.3.1).
  - — If bit 20 is read as 1, the INVEPT instruction is supported.
  - — If bit 25 is read as 1, the single-context INVEPT type is supported.
  - — If bit 26 is read as 1, the all-context INVEPT type is supported.
- If bit 21 is read as 1, accessed and dirty flags for EPT are supported (see Section 28.2.4).
- Support for the INVVPID instruction (see Chapter 30 and Section 28.3.3.1).
  - — If bit 32 is read as 1, the INVVPID instruction is supported.
  - — If bit 40 is read as 1, the individual-address INVVPID type is supported.
  - — If bit 41 is read as 1, the single-context INVVPID type is supported.
  - — If bit 42 is read as 1, the all-context INVVPID type is supported.
  - — If bit 43 is read as 1, the single-context-retaining-globals INVVPID type is supported.
- Bits 5:1, bit 7, bits 13:9, bit 15, bits 19:18, bits 24:22, bits 31:27, bits 39:33, and bits 63:44 are reserved and are read as 0.

The IA32_VMX_EPT_VPID_CAP MSR exists only on processors that support the 1-setting of the "activate secondary controls" VM-execution control (only if bit 63 of the IA32_VMX_PROCBASED_CTLS MSR is 1) and that support either the 1-setting of the "enable EPT" VM-execution control (only if bit 33 of the IA32_VMX_PROCBASED_CTLS2 MSR is 1) or the 1-setting of the "enable VPID" VM-execution control (only if bit 37 of the IA32_VMX_PROCBASED_CTLS2 MSR is 1).

A.11 VM FUNCTIONS

The IA32_VMX_VMFUNC MSR (index 491H) reports on the allowed settings of the VM-function controls (see Section 24.6.14). VM entry allows bit X of the VM-function controls to be 1 if bit X in the MSR is set to 1; if bit X in the MSR is cleared to 0, VM entry fails if bit X of the VM-function controls, the "activate secondary controls" primary processor-based VM-execution control, and the "enable VM functions" secondary processor-based VM-execution control are all 1.

The IA32_VMX_VMFUNC MSR exists only on processors that support the 1-setting of the "activate secondary controls" VM-execution control (only if bit 63 of the IA32_VMX_PROCBASED_CTLS MSR is 1) and the 1-setting of the "enable VM functions" secondary processor-based VM-execution control (only if bit 45 of the IA32_VMX_PROCBASED_CTLS2 MSR is 1).

APPENDIX B
FIELD ENCODING IN VMCS

Every component of the VMCS is encoded by a 32-bit field that can be used by VMREAD and VMWRITE. Section 24.11.2 describes the structure of the encoding space (the meanings of the bits in each 32-bit encoding).

This appendix enumerates all fields in the VMCS and their encodings. Fields are grouped by width (16-bit, 32-bit, etc.) and type (guest-state, host-state, etc.)

B.1 16-BIT FIELDS

A value of 0 in bits 14:13 of an encoding indicates a 16-bit field. Only guest-state areas and the host-state area contain 16-bit fields. As noted in Section 24.11.2, each 16-bit field allows only full access, meaning that bit 0 of its encoding is 0. Each such encoding is thus an even number.

B.1.1 16-Bit Control Fields

A value of 0 in bits 11:10 of an encoding indicates a control field. These fields are distinguished by their index value in bits 9:1. Table B-1 enumerates the 16-bit control fields.

Table B-1. Encoding for 16-Bit Control Fields (0000_00xx_xxxx_xxx0B)

Field Name	Index	Encoding
Virtual-processor identifier (VPID)[1]	000000000B	00000000H
Posted-interrupt notification vector[2]	000000001B	00000002H
EPTP index[3]	000000010B	00000004H

NOTES:

1. This field exists only on processors that support the 1-setting of the "enable VPID" VM-execution control.
2. This field exists only on processors that support the 1-setting of the "process posted interrupts" VM-execution control.
3. This field exists only on processors that support the 1-setting of the "EPT-violation #VE" VM-execution control.

B.1.2 16-Bit Guest-State Fields

A value of 2 in bits 11:10 of an encoding indicates a field in the guest-state area. These fields are distinguished by their index value in bits 9:1. Table B-2 enumerates 16-bit guest-state fields.

Table B-2. Encodings for 16-Bit Guest-State Fields (0000_10xx_xxxx_xxx0B)

Field Name	Index	Encoding
Guest ES selector	000000000B	00000800H
Guest CS selector	000000001B	00000802H
Guest SS selector	000000010B	00000804H
Guest DS selector	000000011B	00000806H
Guest FS selector	000000100B	00000808H
Guest GS selector	000000101B	0000080AH
Guest LDTR selector	000000110B	0000080CH
Guest TR selector	000000111B	0000080EH

Table B-2. Encodings for 16-Bit Guest-State Fields (0000_10xx_xxxx_xxx0B) (Contd.)

Field Name	Index	Encoding
Guest interrupt status[1]	000001000B	00000810H

NOTES:
1. This field exists only on processors that support the 1-setting of the "virtual-interrupt delivery" VM-execution control.

B.1.3 16-Bit Host-State Fields

A value of 3 in bits 11:10 of an encoding indicates a field in the host-state area. These fields are distinguished by their index value in bits 9:1. Table B-3 enumerates the 16-bit host-state fields.

Table B-3. Encodings for 16-Bit Host-State Fields (0000_11xx_xxxx_xxx0B)

Field Name	Index	Encoding
Host ES selector	000000000B	00000C00H
Host CS selector	000000001B	00000C02H
Host SS selector	000000010B	00000C04H
Host DS selector	000000011B	00000C06H
Host FS selector	000000100B	00000C08H
Host GS selector	000000101B	00000C0AH
Host TR selector	000000110B	00000C0CH

B.2 64-BIT FIELDS

A value of 1 in bits 14:13 of an encoding indicates a 64-bit field. There are 64-bit fields only for controls and for guest state. As noted in Section 24.11.2, every 64-bit field has two encodings, which differ on bit 0, the access type. Thus, each such field has an even encoding for full access and an odd encoding for high access.

B.2.1 64-Bit Control Fields

A value of 0 in bits 11:10 of an encoding indicates a control field. These fields are distinguished by their index value in bits 9:1. Table B-4 enumerates the 64-bit control fields.

Table B-4. Encodings for 64-Bit Control Fields (0010_00xx_xxxx_xxxAb)

Field Name	Index	Encoding
Address of I/O bitmap A (full)	000000000B	00002000H
Address of I/O bitmap A (high)		00002001H
Address of I/O bitmap B (full)	000000001B	00002002H
Address of I/O bitmap B (high)		00002003H
Address of MSR bitmaps (full)[1]	000000010B	00002004H
Address of MSR bitmaps (high)[1]		00002005H
VM-exit MSR-store address (full)	000000011B	00002006H
VM-exit MSR-store address (high)		00002007H
VM-exit MSR-load address (full)	000000100B	00002008H
VM-exit MSR-load address (high)		00002009H

Table B-4. Encodings for 64-Bit Control Fields (0010_00xx_xxxx_xxxAb) (Contd.)

Field Name	Index	Encoding
VM-entry MSR-load address (full)	000000101B	0000200AH
VM-entry MSR-load address (high)		0000200BH
Executive-VMCS pointer (full)	000000110B	0000200CH
Executive-VMCS pointer (high)		0000200DH

XSS-exiting bitmap (high)[11]		0000202DH
TSC multiplier (full)[12]	000011001B	00002032H
TSC multiplier (high)[12]		00002033H

NOTES:

1. This field exists only on processors that support the 1-setting of the "use MSR bitmaps" VM-execution control.

2. This field exists only on processors that support either the 1-setting of the "use TPR shadow" VM-execution control.
3. This field exists only on processors that support the 1-setting of the "virtualize APIC accesses" VM-execution control.
4. This field exists only on processors that support the 1-setting of the "process posted interrupts" VM-execution control.
5. This field exists only on processors that support the 1-setting of the "enable VM functions" VM-execution control.
6. This field exists only on processors that support the 1-setting of the "enable EPT" VM-execution control.
7. This field exists only on processors that support the 1-setting of the "virtual-interrupt delivery" VM-execution control.
8. This field exists only on processors that support the 1-setting of the "EPTP switching" VM-function control.
9. This field exists only on processors that support the 1-setting of the "VMCS shadowing" VM-execution control.
10. This field exists only on processors that support the 1-setting of the "EPT-violation #VE" VM-execution control.
11. This field exists only on processors that support the 1-setting of the "enable XSAVES/XRSTORS" VM-execution control.
12. This field exists only on processors that support the 1-setting of the "use TSC scaling" VM-execution control.

B.2.2 64-Bit Read-Only Data Field

A value of 1 in bits 11:10 of an encoding indicates a read-only data field. These fields are distinguished by their index value in bits 9:1. There is only one such 64-bit field as given in Table B-5.(As with other 64-bit fields, this one has two encodings.)

Table B-5. Encodings for 64-Bit Read-Only Data Field (0010_01xx_xxxx_xxxAb)

Field Name	Index	Encoding
Guest-physical address (full)[1]	000000000B	00002400H
Guest-physical address (high)[1]		00002401H

NOTES:
1. This field exists only on processors that support the 1-setting of the "enable EPT" VM-execution control.

B.2.3 64-Bit Guest-State Fields

A value of 2 in bits 11:10 of an encoding indicates a field in the guest-state area. These fields are distinguished by their index value in bits 9:1. Table B-6 enumerates the 64-bit guest-state fields.

Table B-6. Encodings for 64-Bit Guest-State Fields (0010_10xx_xxxx_xxxAb)

Field Name	Index	Encoding
VMCS link pointer (full)	000000000B	00002800H
VMCS link pointer (high)		00002801H
Guest IA32_DEBUGCTL (full)	000000001B	00002802H
Guest IA32_DEBUGCTL (high)		00002803H
Guest IA32_PAT (full)[1]	000000010B	00002804H
Guest IA32_PAT (high)[1]		00002805H
Guest IA32_EFER (full)[2]	000000011B	00002806H
Guest IA32_EFER (high)[2]		00002807H
Guest IA32_PERF_GLOBAL_CTRL (full)[3]	000000100B	00002808H
Guest IA32_PERF_GLOBAL_CTRL (high)[3]		00002809H
Guest PDPTE0 (full)[4]	000000101B	0000280AH
Guest PDPTE0 (high)[4]		0000280BH

Table B-6. Encodings for 64-Bit Guest-State Fields (0010_10xx_xxxx_xxxAb) (Contd.)

Field Name	Index	Encoding
Guest PDPTE1 (full)[4]	000000110B	0000280CH
Guest PDPTE1 (high)[4]		0000280DH
Guest PDPTE2 (full)[4]	000000111B	0000280EH
Guest PDPTE2 (high)[4]		0000280FH
Guest PDPTE3 (full)[4]	000001000B	00002810H
Guest PDPTE3 (high)[4]		00002811H

NOTES:

1. This field exists only on processors that support either the 1-setting of the "load IA32_PAT" VM-entry control or that of the "save IA32_PAT" VM-exit control.
2. This field exists only on processors that support either the 1-setting of the "load IA32_EFER" VM-entry control or that of the "save IA32_EFER" VM-exit control.
3. This field exists only on processors that support the 1-setting of the "load IA32_PERF_GLOBAL_CTRL" VM-entry control.
4. This field exists only on processors that support the 1-setting of the "enable EPT" VM-execution control.

B.2.4 64-Bit Host-State Fields

A value of 3 in bits 11:10 of an encoding indicates a field in the host-state area. These fields are distinguished by their index value in bits 9:1. Table B-7 enumerates the 64-bit control fields.

Table B-7. Encodings for 64-Bit Host-State Fields (0010_11xx_xxxx_xxxAb)

Field Name	Index	Encoding
Host IA32_PAT (full)[1]	000000000B	00002C00H
Host IA32_PAT (high)[1]		00002C01H
Host IA32_EFER (full)[2]	000000001B	00002C02H
Host IA32_EFER (high)[2]		00002C03H
Host IA32_PERF_GLOBAL_CTRL (full)[3]	000000010B	00002C04H
Host IA32_PERF_GLOBAL_CTRL (high)[3]		00002C05H

NOTES:

1. This field exists only on processors that support the 1-setting of the "load IA32_PAT" VM-exit control.
2. This field exists only on processors that support the 1-setting of the "load IA32_EFER" VM-exit control.
3. This field exists only on processors that support the 1-setting of the "load IA32_PERF_GLOBAL_CTRL" VM-exit control.

B.3 32-BIT FIELDS

A value of 2 in bits 14:13 of an encoding indicates a 32-bit field. As noted in Section 24.11.2, each 32-bit field allows only full access, meaning that bit 0 of its encoding is 0. Each such encoding is thus an even number.

B.3.1 32-Bit Control Fields

A value of 0 in bits 11:10 of an encoding indicates a control field. These fields are distinguished by their index value in bits 9:1. Table B-8 enumerates the 32-bit control fields.

Table B-8. Encodings for 32-Bit Control Fields (0100_00xx_xxxx_xxx0B)

Field Name	Index	Encoding
Pin-based VM-execution controls	000000000B	00004000H
Primary processor-based VM-execution controls	000000001B	00004002H
Exception bitmap	000000010B	00004004H
Page-fault error-code mask	000000011B	00004006H
Page-fault error-code match	000000100B	00004008H
CR3-target count	000000101B	0000400AH
VM-exit controls	000000110B	0000400CH
VM-exit MSR-store count	000000111B	0000400EH
VM-exit MSR-load count	000001000B	00004010H
VM-entry controls	000001001B	00004012H
VM-entry MSR-load count	000001010B	00004014H
VM-entry interruption-information field	000001011B	00004016H
VM-entry exception error code	000001100B	00004018H
VM-entry instruction length	000001101B	0000401AH
TPR threshold[1]	000001110B	0000401CH
Secondary processor-based VM-execution controls[2]	000001111b	0000401EH
PLE_Gap[3]	000010000b	00004020H
PLE_Window[3]	000010001b	00004022H

NOTES:

1. This field exists only on processors that support the 1-setting of the "use TPR shadow" VM-execution control.
2. This field exists only on processors that support the 1-setting of the "activate secondary controls" VM-execution control.
3. This field exists only on processors that support the 1-setting of the "PAUSE-loop exiting" VM-execution control.

B.3.2 32-Bit Read-Only Data Fields

A value of 1 in bits 11:10 of an encoding indicates a read-only data field. These fields are distinguished by their index value in bits 9:1. Table B-9 enumerates the 32-bit read-only data fields.

Table B-9. Encodings for 32-Bit Read-Only Data Fields (0100_01xx_xxxx_xxx0B)

Field Name	Index	Encoding
VM-instruction error	000000000B	00004400H
Exit reason	000000001B	00004402H
VM-exit interruption information	000000010B	00004404H
VM-exit interruption error code	000000011B	00004406H
IDT-vectoring information field	000000100B	00004408H
IDT-vectoring error code	000000101B	0000440AH
VM-exit instruction length	000000110B	0000440CH

Table B-9. Encodings for 32-Bit Read-Only Data Fields (0100_01xx_xxxx_xxx0B) (Contd.)

Field Name	Index	Encoding
VM-exit instruction information	000000111B	0000440EH

B.3.3 32-Bit Guest-State Fields

A value of 2 in bits 11:10 of an encoding indicates a field in the guest-state area. These fields are distinguished by their index value in bits 9:1. Table B-10 enumerates the 32-bit guest-state fields.

Table B-10. Encodings for 32-Bit Guest-State Fields (0100_10xx_xxxx_xxx0B)

Field Name	Index	Encoding
Guest ES limit	000000000B	00004800H
Guest CS limit	000000001B	00004802H
Guest SS limit	000000010B	00004804H
Guest DS limit	000000011B	00004806H
Guest FS limit	000000100B	00004808H
Guest GS limit	000000101B	0000480AH
Guest LDTR limit	000000110B	0000480CH
Guest TR limit	000000111B	0000480EH
Guest GDTR limit	000001000B	00004810H
Guest IDTR limit	000001001B	00004812H
Guest ES access rights	000001010B	00004814H
Guest CS access rights	000001011B	00004816H
Guest SS access rights	000001100B	00004818H
Guest DS access rights	000001101B	0000481AH
Guest FS access rights	000001110B	0000481CH
Guest GS access rights	000001111B	0000481EH
Guest LDTR access rights	000010000B	00004820H
Guest TR access rights	000010001B	00004822H
Guest interruptibility state	000010010B	00004824H
Guest activity state	000010011B	00004826H
Guest SMBASE	000010100B	00004828H
Guest IA32_SYSENTER_CS	000010101B	0000482AH
VMX-preemption timer value[1]	000010111B	0000482EH

NOTES:

1. This field exists only on processors that support the 1-setting of the "activate VMX-preemption timer" VM-execution control.

The limit fields for GDTR and IDTR are defined to be 32 bits in width even though these fields are only 16-bits wide in the Intel 64 and IA-32 architectures. VM entry ensures that the high 16 bits of both these fields are cleared to 0.

B.3.4 32-Bit Host-State Field

A value of 3 in bits 11:10 of an encoding indicates a field in the host-state area. There is only one such 32-bit field as given in Table B-11.

Table B-11. Encoding for 32-Bit Host-State Field (0100_11xx_xxxx_xxx0B)

Field Name	Index	Encoding
Host IA32_SYSENTER_CS	000000000B	00004C00H

B.4 NATURAL-WIDTH FIELDS

A value of 3 in bits 14:13 of an encoding indicates a natural-width field. As noted in Section 24.11.2, each of these fields allows only full access, meaning that bit 0 of its encoding is 0. Each such encoding is thus an even number.

B.4.1 Natural-Width Control Fields

A value of 0 in bits 11:10 of an encoding indicates a control field. These fields are distinguished by their index value in bits 9:1. Table B-12 enumerates the natural-width control fields.

Table B-12. Encodings for Natural-Width Control Fields (0110_00xx_xxxx_xxx0B)

Field Name	Index	Encoding
CR0 guest/host mask	000000000B	00006000H
CR4 guest/host mask	000000001B	00006002H
CR0 read shadow	000000010B	00006004H
CR4 read shadow	000000011B	00006006H
CR3-target value 0	000000100B	00006008H
CR3-target value 1	000000101B	0000600AH
CR3-target value 2	000000110B	0000600CH
CR3-target value 3[1]	000000111B	0000600EH

NOTES:

1. If a future implementation supports more than 4 CR3-target values, they will be encoded consecutively following the 4 encodings given here.

B.4.2 Natural-Width Read-Only Data Fields

A value of 1 in bits 11:10 of an encoding indicates a read-only data field. These fields are distinguished by their index value in bits 9:1. Table B-13 enumerates the natural-width read-only data fields.

Table B-13. Encodings for Natural-Width Read-Only Data Fields (0110_01xx_xxxx_xxx0B)

Field Name	Index	Encoding
Exit qualification	000000000B	00006400H
I/O RCX	000000001B	00006402H
I/O RSI	000000010B	00006404H
I/O RDI	000000011B	00006406H
I/O RIP	000000100B	00006408H
Guest-linear address	000000101B	0000640AH

B.4.3 Natural-Width Guest-State Fields

A value of 2 in bits 11:10 of an encoding indicates a field in the guest-state area. These fields are distinguished by their index value in bits 9:1. Table B-14 enumerates the natural-width guest-state fields.

Table B-14. Encodings for Natural-Width Guest-State Fields (0110_10xx_xxxx_xxx0B)

Field Name	Index	Encoding
Guest CR0	000000000B	00006800H
Guest CR3	000000001B	00006802H
Guest CR4	000000010B	00006804H
Guest ES base	000000011B	00006806H
Guest CS base	000000100B	00006808H
Guest SS base	000000101B	0000680AH
Guest DS base	000000110B	0000680CH
Guest FS base	000000111B	0000680EH
Guest GS base	000001000B	00006810H
Guest LDTR base	000001001B	00006812H
Guest TR base	000001010B	00006814H
Guest GDTR base	000001011B	00006816H
Guest IDTR base	000001100B	00006818H
Guest DR7	000001101B	0000681AH
Guest RSP	000001110B	0000681CH
Guest RIP	000001111B	0000681EH
Guest RFLAGS	000010000B	00006820H
Guest pending debug exceptions	000010001B	00006822H
Guest IA32_SYSENTER_ESP	000010010B	00006824H
Guest IA32_SYSENTER_EIP	000010011B	00006826H

The base-address fields for ES, CS, SS, and DS in the guest-state area are defined to be natural-width (with 64 bits on processors supporting Intel 64 architecture) even though these fields are only 32-bits wide in the Intel 64 architecture. VM entry ensures that the high 32 bits of these fields are cleared to 0.

B.4.4 Natural-Width Host-State Fields

A value of 3 in bits 11:10 of an encoding indicates a field in the host-state area. These fields are distinguished by their index value in bits 9:1. Table B-15 enumerates the natural-width host-state fields.

Table B-15. Encodings for Natural-Width Host-State Fields (0110_11xx_xxxx_xxx0B)

Field Name	Index	Encoding

Host RIP	000001011B	00006C16H

APPENDIX C
VMX BASIC EXIT REASONS

Every VM exit writes a 32-bit exit reason to the VMCS (see Section 24.9.1). Certain VM-entry failures also do this (see Section 26.7). The low 16 bits of the exit-reason field form the basic exit reason which provides basic information about the cause of the VM exit or VM-entry failure.

Table C-1 lists values for basic exit reasons and explains their meaning. Entries apply to VM exits, unless otherwise noted.

Table C-1. Basic Exit Reasons

Basic Exit Reason	Description
0	**Exception or non-maskable interrupt (NMI).** Either: 1: Guest software caused an exception and the bit in the exception bitmap associated with exception's vector was 1. 2: An NMI was delivered to the logical processor and the "NMI exiting" VM-execution control was 1. This case includes executions of BOUND that cause #BR, executions of INT3 (they cause #BP), executions of INTO that cause #OF, and executions of UD2 (they cause #UD).
1	**External interrupt.** An external interrupt arrived and the "external-interrupt exiting" VM-execution control was 1.
2	**Triple fault.** The logical processor encountered an exception while attempting to call the double-fault handler and that exception did not itself cause a VM exit due to the exception bitmap.
3	**INIT signal.** An INIT signal arrived
4	**Start-up IPI (SIPI).** A SIPI arrived while the logical processor was in the "wait-for-SIPI" state.
5	**I/O system-management interrupt (SMI).** An SMI arrived immediately after retirement of an I/O instruction and caused an SMM VM exit (see Section 34.15.2).
6	**Other SMI.** An SMI arrived and caused an SMM VM exit (see Section 34.15.2) but not immediately after retirement of an I/O instruction.
7	**Interrupt window.** At the beginning of an instruction, RFLAGS.IF was 1; events were not blocked by STI or by MOV SS; and the "interrupt-window exiting" VM-execution control was 1.
8	**NMI window.** At the beginning of an instruction, there was no virtual-NMI blocking; events were not blocked by MOV SS; and the "NMI-window exiting" VM-execution control was 1.
9	**Task switch.** Guest software attempted a task switch.
10	**CPUID.** Guest software attempted to execute CPUID.
11	**GETSEC.** Guest software attempted to execute GETSEC.
12	**HLT.** Guest software attempted to execute HLT and the "HLT exiting" VM-execution control was 1.
13	**INVD.** Guest software attempted to execute INVD.
14	**INVLPG.** Guest software attempted to execute INVLPG and the "INVLPG exiting" VM-execution control was 1.
15	**RDPMC.** Guest software attempted to execute RDPMC and the "RDPMC exiting" VM-execution control was 1.
16	**RDTSC.** Guest software attempted to execute RDTSC and the "RDTSC exiting" VM-execution control was 1.
17	**RSM.** Guest software attempted to execute RSM in SMM.
18	**VMCALL.** VMCALL was executed either by guest software (causing an ordinary VM exit) or by the executive monitor (causing an SMM VM exit; see Section 34.15.2).
19	**VMCLEAR.** Guest software attempted to execute VMCLEAR.
20	**VMLAUNCH.** Guest software attempted to execute VMLAUNCH.
21	**VMPTRLD.** Guest software attempted to execute VMPTRLD.
22	**VMPTRST.** Guest software attempted to execute VMPTRST.
23	**VMREAD.** Guest software attempted to execute VMREAD.

Table C-1. Basic Exit Reasons (Contd.)

Basic Exit Reason	Description
24	**VMRESUME.** Guest software attempted to execute VMRESUME.
25	**VMWRITE.** Guest software attempted to execute VMWRITE.
26	**VMXOFF.** Guest software attempted to execute VMXOFF.
27	**VMXON.** Guest software attempted to execute VMXON.
28	**Control-register accesses.** Guest software attempted to access CR0, CR3, CR4, or CR8 using CLTS, LMSW, or MOV CR and the VM-execution control fields indicate that a VM exit should occur (see Section 25.1 for details). This basic exit reason is not used for trap-like VM exits following executions of the MOV to CR8 instruction when the "use TPR shadow" VM-execution control is 1.
29	**MOV DR.** Guest software attempted a MOV to or from a debug register and the "MOV-DR exiting" VM-execution control was 1.
30	**I/O instruction.** Guest software attempted to execute an I/O instruction and either: 1: The "use I/O bitmaps" VM-execution control was 0 and the "unconditional I/O exiting" VM-execution control was 1. 2: The "use I/O bitmaps" VM-execution control was 1 and a bit in the I/O bitmap associated with one of the ports accessed by the I/O instruction was 1.
31	**RDMSR.** Guest software attempted to execute RDMSR and either: 1: The "use MSR bitmaps" VM-execution control was 0. 2: The value of RCX is neither in the range 00000000H – 00001FFFH nor in the range C0000000H – C0001FFFH. 3: The value of RCX was in the range 00000000H – 00001FFFH and the n^{th} bit in read bitmap for low MSRs is 1, where n was the value of RCX. 4: The value of RCX is in the range C0000000H – C0001FFFH and the n^{th} bit in read bitmap for high MSRs is 1, where n is the value of RCX & 00001FFFH.
32	**WRMSR.** Guest software attempted to execute WRMSR and either: 1: The "use MSR bitmaps" VM-execution control was 0. 2: The value of RCX is neither in the range 00000000H – 00001FFFH nor in the range C0000000H – C0001FFFH. 3: The value of RCX was in the range 00000000H – 00001FFFH and the n^{th} bit in write bitmap for low MSRs is 1, where n was the value of RCX. 4: The value of RCX is in the range C0000000H – C0001FFFH and the n^{th} bit in write bitmap for high MSRs is 1, where n is the value of RCX & 00001FFFH.
33	**VM-entry failure due to invalid guest state.** A VM entry failed one of the checks identified in Section 26.3.1.
34	**VM-entry failure due to MSR loading.** A VM entry failed in an attempt to load MSRs. See Section 26.4.
36	**MWAIT.** Guest software attempted to execute MWAIT and the "MWAIT exiting" VM-execution control was 1.
37	**Monitor trap flag.** A VM entry occurred due to the 1-setting of the "monitor trap flag" VM-execution control and injection of an MTF VM exit as part of VM entry. See Section 25.5.2.
39	**MONITOR.** Guest software attempted to execute MONITOR and the "MONITOR exiting" VM-execution control was 1.
40	**PAUSE.** Either guest software attempted to execute PAUSE and the "PAUSE exiting" VM-execution control was 1 or the "PAUSE-loop exiting" VM-execution control was 1 and guest software executed a PAUSE loop with execution time exceeding PLE_Window (see Section 25.1.3).
41	**VM-entry failure due to machine-check event.** A machine-check event occurred during VM entry (see Section 26.8).
43	**TPR below threshold.** The logical processor determined that the value of bits 7:4 of the byte at offset 080H on the virtual-APIC page was below that of the TPR threshold VM-execution control field while the "use TPR shadow" VM-execution control was 1 either as part of TPR virtualization (Section 29.1.2) or VM entry (Section 26.6.7).
44	**APIC access.** Guest software attempted to access memory at a physical address on the APIC-access page and the "virtualize APIC accesses" VM-execution control was 1 (see Section 29.4).
45	**Virtualized EOI.** EOI virtualization was performed for a virtual interrupt whose vector indexed a bit set in the EOI-exit bitmap.

Table C-1. Basic Exit Reasons (Contd.)

Basic Exit Reason	Description
46	**Access to GDTR or IDTR.** Guest software attempted to execute LGDT, LIDT, SGDT, or SIDT and the "descriptor-table exiting" VM-execution control was 1.
47	**Access to LDTR or TR.** Guest software attempted to execute LLDT, LTR, SLDT, or STR and the "descriptor-table exiting" VM-execution control was 1.
48	**EPT violation.** An attempt to access memory with a guest-physical address was disallowed by the configuration of the EPT paging structures.
49	**EPT misconfiguration.** An attempt to access memory with a guest-physical address encountered a misconfigured EPT paging-structure entry.
50	**INVEPT.** Guest software attempted to execute INVEPT.
51	**RDTSCP.** Guest software attempted to execute RDTSCP and the "enable RDTSCP" and "RDTSC exiting" VM-execution controls were both 1.
52	**VMX-preemption timer expired.** The preemption timer counted down to zero.
53	**INVVPID.** Guest software attempted to execute INVVPID.
54	**WBINVD.** Guest software attempted to execute WBINVD and the "WBINVD exiting" VM-execution control was 1.
55	**XSETBV.** Guest software attempted to execute XSETBV.
56	**APIC write.** Guest software completed a write to the virtual-APIC page that must be virtualized by VMM software (see Section 29.4.3.3).
57	**RDRAND.** Guest software attempted to execute RDRAND and the "RDRAND exiting" VM-execution control was 1.
58	**INVPCID.** Guest software attempted to execute INVPCID and the "enable INVPCID" and "INVLPG exiting" VM-execution controls were both 1.
59	**VMFUNC.** Guest software invoked a VM function with the VMFUNC instruction and the VM function either was not enabled or generated a function-specific condition causing a VM exit.
61	**RDSEED.** Guest software attempted to execute RDSEED and the "RDSEED exiting" VM-execution control was 1.
63	**XSAVES.** Guest software attempted to execute XSAVES, the "enable XSAVES/XRSTORS" was 1, and a bit was set in the logical-AND of the following three values: EDX:EAX, the IA32_XSS MSR, and the XSS-exiting bitmap.
64	**XRSTORS.** Guest software attempted to execute XRSTORS, the "enable XSAVES/XRSTORS" was 1, and a bit was set in the logical-AND of the following three values: EDX:EAX, the IA32_XSS MSR, and the XSS-exiting bitmap.

bootstrap processor, Vol.2-5-15, Vol.2-5-20, Vol.2-5-28, Vol.2-5-29
BOUND instruction, Vol.1-6-13, Vol.1-7-18, Vol.1-7-23, Vol.2-3-97, Vol.2-4-433, Vol.3-2-5, Vol.3-6-4, Vol.3-6-25
BOUND range exceeded exception (#BR), Vol.1-6-13, Vol.2-3-97, Vol.2-4-433, Vol.3-6-25
BP register, Vol.1-3-12
BP0#, BP1#, BP2#, and BP3# pins, Vol.3-17-35, Vol.3-17-37
Branch
control transfer instructions, Vol.1-7-14
hints, Vol.1-11-13
on EFLAGS register status flags, Vol.1-7-15, Vol.1-8-6
on x87 FPU condition codes, Vol.1-8-6, Vol.1-8-20
prediction, Vol.1-2-8
Branch hints, Vol.2-2-2
Branch record
branch trace message, Vol.3-17-13
IA-32e mode, Vol.3-17-20
saving, Vol.3-17-15, Vol.3-17-24, Vol.3-17-32
saving as a branch trace message, Vol.3-17-13
structure, Vol.3-17-33
structure of in BTS buffer, Vol.3-17-19
Branch trace message (see BTM)
Branch trace store (see BTS)
Brand information, Vol.2-3-202
processor brand index, Vol.2-3-204
processor brand string, Vol.2-3-202
Breakpoint exception (#BP), Vol.3-6-4, Vol.3-6-23, Vol.3-17-10
Breakpoints
data breakpoint, Vol.3-17-5
data breakpoint exception conditions, Vol.3-17-9
description of, Vol.3-17-1
DR0-DR3 debug registers, Vol.3-17-3
example, Vol.3-17-5
exception, Vol.3-6-23
field recognition, Vol.3-17-5, Vol.3-17-6
general-detect exception condition, Vol.3-17-9
instruction breakpoint, Vol.3-17-5
instruction breakpoint exception condition, Vol.3-17-8
I/O breakpoint exception conditions, Vol.3-17-9
LEN0 - LEN3 (Length) fields
DR7 register, Vol.3-17-5
R/W0-R/W3 (read/write) fields
DR7 register, Vol.3-17-4
single-step exception condition, Vol.3-17-9
task-switch exception condition, Vol.3-17-10
BS (single step) flag, DR6 register, Vol.3-17-3
BSF instruction, Vol.1-7-14, Vol.2-3-99
BSP flag, IA32_APIC_BASE MSR, Vol.3-10-8
BSR instruction, Vol.1-7-14, Vol.2-3-101
BSWAP instruction, Vol.1-7-4, Vol.2-3-103, Vol.3-22-4
BT instruction, Vol.1-3-15, Vol.1-3-16, Vol.1-7-14, Vol.2-3-104
BT (task switch) flag, DR6 register, Vol.3-17-3, Vol.3-17-10
BTC instruction, Vol.1-3-15, Vol.1-3-16, Vol.1-7-14, Vol.2-3-106, Vol.2-3-490, Vol.3-8-3
BTF (single-step on branches) flag
DEBUGCTLMSR MSR, Vol.3-17-37
BTMs (branch trace messages)
description of, Vol.3-17-13
enabling, Vol.3-17-11, Vol.3-17-22, Vol.3-17-23, Vol.3-17-32, Vol.3-17-34, Vol.3-17-35
TR (trace message enable) flag
MSR_DEBUGCTLA MSR, Vol.3-17-32
MSR_DEBUGCTLB MSR, Vol.3-17-11, Vol.3-17-34, Vol.3-17-35
BTR instruction, Vol.1-3-15, Vol.1-3-16, Vol.1-7-14, Vol.2-3-108, Vol.2-3-490, Vol.3-8-3
BTS buffer
description of, Vol.3-17-17
introduction to, Vol.3-17-11, Vol.3-17-13
records in, Vol.3-17-19
setting up, Vol.3-17-22
structure of, Vol.3-17-18, Vol.3-17-20, Vol.3-18-31
BTS instruction, Vol.1-3-15, Vol.1-3-16, Vol.1-7-14, Vol.2-3-110, Vol.2-3-490, Vol.3-8-3
BTS (branch trace store) facilities
availability of, Vol.3-17-31
BTS_UNAVAILABLE flag, IA32_MISC_ENABLE MSR, Vol.3-17-17, Vol.1-35-239
introduction to, Vol.3-17-11
setting up BTS buffer, Vol.3-17-22
writing an interrupt service routine for, Vol.3-17-23
BTS_UNAVAILABLE, Vol.3-17-17
Built-in self-test (BIST)
description of, Vol.3-9-1
performing, Vol.3-9-2
Bus
errors detected with MCA, Vol.3-15-26
hold, Vol.3-22-34
locking, Vol.3-8-3, Vol.3-22-34
BX register, Vol.1-3-12
Byte, Vol.1-4-1
Byte order, Vol.1-1-5, Vol.2-1-4, Vol.3-1-6

C

C (conforming) flag, segment descriptor, Vol.3-5-11
C1 flag, x87 FPU status word, Vol.1-8-4, Vol.1-8-27, Vol.1-8-30, Vol.1-8-31, Vol.3-22-7, Vol.3-22-14
C2 flag, x87 FPU status word, Vol.1-8-5, Vol.3-22-7
Cache and TLB information, Vol.2-3-196
Cache control, Vol.3-11-20
adaptive mode, L1 Data Cache, Vol.3-11-18
cache management instructions, Vol.3-11-17, Vol.3-11-18

cache mechanisms in IA-32 processors, Vol.3-22-29
caching terminology, Vol.3-11-5
CD flag, CR0 control register, Vol.3-11-10, Vol.3-22-18
choosing a memory type, Vol.3-11-8
CPUID feature flag, Vol.3-11-18
flags and fields, Vol.3-11-10
flushing TLBs, Vol.3-11-19
G (global) flag
page-directory entries, Vol.3-11-13
page-table entries, Vol.3-11-13
internal caches, Vol.3-11-1
MemTypeGet() function, Vol.3-11-29
MemTypeSet() function, Vol.3-11-31
MESI protocol, Vol.3-11-5, Vol.3-11-9
methods of caching available, Vol.3-11-6
MTRR initialization, Vol.3-11-29
MTRR precedences, Vol.3-11-28
MTRRs, description of, Vol.3-11-20
multiple-processor considerations, Vol.3-11-32
NW flag, CR0 control register, Vol.3-11-13, Vol.3-22-18
operating modes, Vol.3-11-12
overview of, Vol.3-11-1
page attribute table (PAT), Vol.3-11-33
PCD flag
CR3 control register, Vol.3-11-13
page-directory entries, Vol.3-11-13, Vol.3-11-33
page-table entries, Vol.3-11-13, Vol.3-11-33
PGE (page global enable) flag, CR4 control register, Vol.3-11-13
precedence of controls, Vol.3-11-13
preventing caching, Vol.3-11-16
protocol, Vol.3-11-9
PWT flag
CR3 control register, Vol.3-11-13
page-directory entries, Vol.3-11-33
page-table entries, Vol.3-11-33
remapping memory types, Vol.3-11-29
setting up memory ranges with MTRRs, Vol.3-11-22
shared mode, L1 Data Cache, Vol.3-11-18
variable-range MTRRs, Vol.3-11-23, Vol.3-11-25
Cache Inclusiveness, Vol.2-3-181
Caches, Vol.3-2-7
cache hit, Vol.3-11-5
cache line, Vol.3-11-5
cache line fill, Vol.3-11-5
cache write hit, Vol.3-11-5
description of, Vol.3-11-1
effects of a locked operation on internal processor caches, Vol.3-8-5
enabling, Vol.3-9-7
management, instructions, Vol.3-2-23, Vol.3-11-17
Caches, invalidating (flushing), Vol.2-3-439, Vol.2-4-556
cache, smart, Vol.1-2-4
Caching
cache control protocol, Vol.3-11-9
cache line, Vol.3-11-5
cache management instructions, Vol.3-11-17
cache mechanisms in IA-32 processors, Vol.3-22-29
caching terminology, Vol.3-11-5
choosing a memory type, Vol.3-11-8
flushing TLBs, Vol.3-11-19
implicit caching, Vol.3-11-19
internal caches, Vol.3-11-1
L1 (level 1) cache, Vol.3-11-4
L2 (level 2) cache, Vol.3-11-4
L3 (level 3) cache, Vol.3-11-4
methods of caching available, Vol.3-11-6
MTRRs, description of, Vol.3-11-20
operating modes, Vol.3-11-12
overview of, Vol.3-11-1
self-modifying code, effect on, Vol.3-11-18, Vol.3-22-29
snooping, Vol.3-11-6
store buffer, Vol.3-11-20
TLBs, Vol.3-11-5
UC (strong uncacheable) memory type, Vol.3-11-6
UC- (uncacheable) memory type, Vol.3-11-6
WB (write back) memory type, Vol.3-11-7
WC (write combining) memory type, Vol.3-11-7
WP (write protected) memory type, Vol.3-11-7
write-back caching, Vol.3-11-6
WT (write through) memory type, Vol.3-11-7
Call gate, Vol.1-6-7
Call gates
16-bit, interlevel return from, Vol.3-22-32
accessing a code segment through, Vol.3-5-15
description of, Vol.3-5-13
for 16-bit and 32-bit code modules, Vol.3-21-1
IA-32e mode, Vol.3-5-14
introduction to, Vol.3-2-4
mechanism, Vol.3-5-15
privilege level checking rules, Vol.3-5-16
CALL instruction, Vol.1-3-18, Vol.1-6-3, Vol.1-6-4, Vol.1-6-7, Vol.1-7-15, Vol.1-7-22, Vol.2-3-114, Vol.3-2-5, Vol.3-3-9, Vol.3-5-10, Vol.3-5-15, Vol.3-5-20, Vol.3-7-2, Vol.3-7-9, Vol.3-7-10, Vol.3-21-5
Caller access privileges, checking, Vol.3-5-26
Calls
16 and 32-bit code segments, Vol.3-21-3
controlling operand-size attribute, Vol.3-21-5
returning from, Vol.3-5-20
Calls (see Procedure calls)
Canonical address, Vol.1-3-10
GETSEC, Vol.2-5-2
Capability MSRs
See VMX capability MSRs
Catastrophic shutdown detector
Thermal monitoring
catastrophic shutdown detector, Vol.3-14-21
catastrophic shutdown detector, Vol.3-14-20
CBW instruction, Vol.1-7-7, Vol.2-3-127
CC0 and CC1 (counter control) fields, CESR MSR (Pentium processor), Vol.3-18-110
CD (cache disable) flag, CR0 control register, Vol.3-2-14, Vol.3-9-7, Vol.3-11-10, Vol.3-11-12, Vol.3-11-13, Vol.3-11-16, Vol.3-11-32, Vol.3-22-17, Vol.3-22-18, Vol.3-22-29
CDQ instruction, Vol.1-7-7, Vol.2-3-250
CDQE instruction, Vol.2-3-127
Celeron processor
description of, Vol.1-2-3
CESR (control and event select) MSR (Pentium processor), Vol.3-18-109, Vol.3-18-110
CF (carry) flag, EFLAGS register, Vol.1-3-16, Vol.1-A-1, Vol.2-3-29, Vol.2-3-104, Vol.2-3-106, Vol.2-3-108, Vol.2-3-110, Vol.2-3-129, Vol.2-3-138, Vol.2-3-255, Vol.2-3-413, Vol.2-3-419, Vol.2-3-611, Vol.2-4-282, Vol.2-4-347, Vol.2-4-359, Vol.2-4-362, Vol.2-4-396
CH register, Vol.1-3-12
CL register, Vol.1-3-12
CLC instruction, Vol.1-3-16, Vol.1-7-21, Vol.2-3-129
CLD instruction, Vol.1-3-17, Vol.1-7-21, Vol.2-3-130
CLFLSH feature flag, CPUID instruction, Vol.3-9-8
CLFLUSH instruction, Vol.1-11-12, Vol.2-3-131, Vol.2-3-133, Vol.3-2-15, Vol.3-9-8, Vol.3-11-17

MSRs supported by, Vol.1-35-265
time-stamp counter, Vol.3-17-38
Pentium Pro processor, Vol.1-1-2, Vol.2-1-2, Vol.3-1-2
description of, Vol.1-2-2
P6 family microarchitecture, Vol.1-2-7
Pentium processor, Vol.1-1-1, Vol.2-1-1, Vol.3-1-1, Vol.3-22-6
compatibility with MCA, Vol.3-15-1
history of, Vol.1-2-2
list of performance-monitoring events, Vol.3-19-208
MSR supported by, Vol.1-35-280
performance-monitoring counters, Vol.3-18-109
Pentium processor Extreme Edition
introduction, Vol.1-2-4
Pentium processor family processors
machine encodings, Vol.2-B-37
Pentium processor with MMX technology, Vol.1-2-2
PerfCtr0 and PerfCtr1 MSRs
(P6 family processors), Vol.3-18-107, Vol.3-18-108
PerfEvtSel0 and PerfEvtSel1 MSRs
(P6 family processors), Vol.3-18-107
PerfEvtSel0 and PerfEvtSel1 MSRs (P6 family processors), Vol.3-18-107
Performance events
architectural, Vol.3-18-1
Intel Core Solo and Intel Core Duo processors, Vol.3-18-1
non-architectural, Vol.3-18-1
non-retirement events (Pentium 4 processor), Vol.3-19-168
P6 family processors, Vol.3-19-199
Pentium 4 and Intel Xeon processors, Vol.3-17-31
Pentium M processors, Vol.3-17-35
Pentium processor, Vol.3-19-208
Performance monitoring counters, Vol.1-3-4
Performance state, Vol.3-14-1
Performance-monitoring counters
counted events (P6 family processors), Vol.3-19-199
counted events (Pentium 4 processor), Vol.3-19-1, Vol.3-19-168
counted events (Pentium processors), Vol.3-18-111
CPUID inquiry for, Vol.2-3-201
description of, Vol.3-18-1, Vol.3-18-2
events that can be counted (Pentium processors), Vol.3-19-208
interrupt, Vol.3-10-1
introduction of in IA-32 processors, Vol.3-22-36
monitoring counter overflow (P6 family processors), Vol.3-18-109
overflow, monitoring (P6 family processors), Vol.3-18-109
overview of, Vol.3-2-7
P6 family processors, Vol.3-18-106
Pentium II processor, Vol.3-18-106
Pentium Pro processor, Vol.3-18-106
Pentium processor, Vol.3-18-109
reading, Vol.3-2-24, Vol.3-18-108
setting up (P6 family processors), Vol.3-18-107
software drivers for, Vol.3-18-108
starting and stopping, Vol.3-18-108
PEXT - Parallel Bits Extract, Vol.2-4-93
PEXTRW instruction, Vol.1-10-11, Vol.2-4-98
PF (parity) flag, EFLAGS register, Vol.1-3-16, Vol.1-A-1
PG (paging) flag
CR0 control register, Vol.3-2-14, Vol.3-5-1
PG (paging) flag, CR0 control register, Vol.3-9-10, Vol.3-9-12, Vol.3-22-31, Vol.3-34-9
PGE (page global enable) flag, CR4 control register, Vol.3-2-17, Vol.3-11-13, Vol.3-22-17, Vol.3-22-18
PHADDD instruction, Vol.1-5-22, Vol.1-12-7, Vol.2-4-101
PHADDSW instruction, Vol.1-5-22, Vol.1-12-7, Vol.2-4-105
PHADDW instruction, Vol.1-5-22, Vol.1-12-7, Vol.2-4-101
PHSUBD instruction, Vol.1-5-22, Vol.1-12-7, Vol.2-4-109
PHSUBSW instruction, Vol.1-5-22, Vol.1-12-7, Vol.2-4-112
PHSUBW instruction, Vol.1-5-22, Vol.1-12-7, Vol.2-4-109
PhysBase field, IA32_MTRR_PHYSBASEn MTRR, Vol.3-11-24, Vol.3-11-26

RFLAGS register, Vol.1-7-22
See EFLAGS register
RIP register, Vol.1-6-4
64-bit mode, Vol.1-7-2
description of, Vol.1-3-18
relation to EIP, Vol.1-7-2
RIP-relative addressing, Vol.2-2-12
ROL instruction, Vol.1-7-13, Vol.2-4-280
ROR instruction, Vol.1-7-13, Vol.2-4-280
RORX - Rotate Right Logical Without Affecting Flags, Vol.2-4-320
Rounding
modes, floating-point operations, Vol.1-4-18, Vol.2-4-322
modes, x87 FPU, Vol.1-8-8
toward zero (truncation), Vol.1-4-18
Rounding control (RC) field
MXCSR register, Vol.1-4-18, Vol.1-10-4, Vol.2-4-322
x87 FPU control word, Vol.1-4-18, Vol.1-8-8, Vol.2-4-322
Rounding, round to integer, x87 FPU operation, Vol.2-3-343
RPL
description of, Vol.3-3-8, Vol.3-5-8
field, segment selector, Vol.3-5-2
RPL field, Vol.2-3-66
RSI register, Vol.1-3-12
RSM instruction, Vol.2-4-331, Vol.3-2-24, Vol.3-8-17, Vol.3-22-5, Vol.3-25-4, Vol.3-34-1, Vol.3-34-2, Vol.3-34-3, Vol.3-34-13, Vol.3-34-15, Vol.3-34-18
RSP register, Vol.1-3-12, Vol.1-6-4
RSQRTPS instruction, Vol.1-10-8, Vol.2-4-333
RSQRTSS instruction, Vol.1-10-8, Vol.2-4-335
RsvdZ, Vol.3-10-40
R/m field, instruction format, Vol.2-2-3
R/S# pin, Vol.3-6-3
R/W (read/write) flag
page-directory entry, Vol.3-5-1, Vol.3-5-2, Vol.3-5-28
page-table entry, Vol.3-5-1, Vol.3-5-2, Vol.3-5-28
R/W0-R/W3 (read/write) fields
DR7 register, Vol.3-17-4, Vol.3-22-19

S

S (descriptor type) flag
segment descriptor, Vol.3-3-11, Vol.3-3-12, Vol.3-5-2, Vol.3-5-5
Safer Mode Extensions, Vol.2-5-1
SAHF instruction, Vol.1-3-15, Vol.1-7-21, Vol.2-4-337
SAL instruction, Vol.1-7-10, Vol.2-4-339
SAR instruction, Vol.1-7-11, Vol.2-4-339
Saturation arithmetic (MMX instructions), Vol.1-9-4
SBB instruction, Vol.1-7-8, Vol.2-3-490, Vol.2-4-346, Vol.3-8-3
Scalar operations
defined, Vol.1-10-7, Vol.1-11-5
scalar double-precision FP operands, Vol.1-11-5
scalar single-precision FP operands, Vol.1-10-7
Scale (operand addressing), Vol.1-3-22, Vol.1-3-23, Vol.1-3-24, Vol.2-2-3
Scale, x87 FPU operation, Vol.1-8-22, Vol.2-3-349
Scaling bias value, Vol.1-8-30
Scan string instructions, Vol.2-4-349
SCAS instruction, Vol.1-3-17, Vol.1-7-18, Vol.2-4-307, Vol.2-4-349
SCASB instruction, Vol.2-4-349
SCASD instruction, Vol.2-4-349
SCASW instruction, Vol.2-4-349
Segment
defined, Vol.1-3-7
descriptor, segment limit, Vol.2-3-497
limit, Vol.2-3-497
maximum number, Vol.1-3-7
registers, moving values to and from, Vol.2-3-528
selector, RPL field, Vol.2-3-66
Segment descriptors
access rights, Vol.3-5-24
access rights, invalid values, Vol.3-22-18
automatic bus locking while updating, Vol.3-8-3
base address fields, Vol.3-3-10
code type, Vol.3-5-2
data type, Vol.3-5-2
description of, Vol.3-2-4, Vol.3-3-9
DPL (descriptor privilege level) field, Vol.3-3-11, Vol.3-5-2
D/B (default operation size/default stack pointer size and/or upper bound) flag, Vol.3-3-11, Vol.3-5-4
E (expansion direction) flag, Vol.3-5-2, Vol.3-5-4
G (granularity) flag, Vol.3-3-11, Vol.3-5-2, Vol.3-5-4
limit field, Vol.3-5-2, Vol.3-5-4
loading, Vol.3-22-19
P (segment-present) flag, Vol.3-3-11
S (descriptor type) flag, Vol.3-3-11, Vol.3-3-12, Vol.3-5-2, Vol.3-5-5
segment limit field, Vol.3-3-10
system type, Vol.3-5-2
tables, Vol.3-3-14
TSS descriptor, Vol.3-7-5, Vol.3-7-6

type field, Vol.3-3-10, Vol.3-3-12, Vol.3-5-2, Vol.3-5-5
type field, encoding, Vol.3-3-14
when P (segment-present) flag is clear, Vol.3-3-11
Segment limit
checking, Vol.3-2-22
field, segment descriptor, Vol.3-3-10
Segment not present exception (#NP), Vol.3-3-11
Segment override prefixes, Vol.1-3-21
Segment registers
64-bit mode, Vol.1-3-15, Vol.1-3-22, Vol.1-7-2
default usage rules, Vol.1-3-21
description of, Vol.1-3-11, Vol.1-3-13, Vol.3-3-8
IA-32e mode, Vol.3-3-9
part of basic programming environment, Vol.1-7-1
saved in TSS, Vol.3-7-4
Segment selector
description of, Vol.1-3-7, Vol.1-3-13
segment override prefixes, Vol.1-3-21
specifying, Vol.1-3-21
Segment selectors
description of, Vol.3-3-7
index field, Vol.3-3-7
null, Vol.3-5-6
null in 64-bit mode, Vol.3-5-6
RPL field, Vol.3-3-8, Vol.3-5-2
TI (table indicator) flag, Vol.3-3-7
Segmented addressing, Vol.2-1-5, Vol.3-1-7
Segmented memory model, Vol.1-1-6, Vol.1-3-7, Vol.1-3-13
Segment-not-present exception (#NP), Vol.3-6-34
Segments
64-bit mode, Vol.3-3-5
basic flat model, Vol.3-3-3
code type, Vol.3-3-12
combining segment, page-level protection, Vol.3-5-29
combining with paging, Vol.3-3-5
compatibility mode, Vol.3-3-5
data type, Vol.3-3-12
defined, Vol.3-3-1
disabling protection of, Vol.3-5-1
enabling protection of, Vol.3-5-1
mapping to pages, Vol.3-4-47
multisegment usage model, Vol.3-3-4
protected flat model, Vol.3-3-3
segment-level protection, Vol.3-5-2, Vol.3-5-3
segment-not-present exception, Vol.3-6-34
system, Vol.3-2-4
types, checking access rights, Vol.3-5-24
typing, Vol.3-5-5
using, Vol.3-3-2
wraparound, Vol.3-22-33
SELF IPI register, Vol.3-10-38
Self Snoop, Vol.2-3-196
Self-modifying code, effect on caches, Vol.3-11-18
GETSEC, Vol.2-5-2, Vol.2-5-3, Vol.2-5-5
SENTER sleep state, Vol.2-5-9
Serialization of I/O instructions, Vol.1-17-5
Serializing, Vol.3-8-17
Serializing instructions, Vol.1-17-5
CPUID, Vol.3-8-17
HT technology, Vol.3-8-29
non-privileged, Vol.3-8-17
privileged, Vol.3-8-17
SETcc instructions, Vol.1-3-17, Vol.1-7-14, Vol.2-4-353
GETSEC, Vol.2-5-4
SF (sign) flag, EFLAGS register, Vol.1-3-16, Vol.1-A-1, Vol.2-3-29
SF (stack fault) flag, x87 FPU status word, Vol.1-8-6, Vol.1-8-27, Vol.3-22-8
SFENCE instruction, Vol.1-10-14, Vol.1-11-12, Vol.1-11-25, Vol.2-4-356, Vol.3-2-15, Vol.3-8-6, Vol.3-8-15, Vol.3-8-16, Vol.3-8-17
SGDT instruction, Vol.2-4-357, Vol.3-2-22, Vol.3-3-15
SHAF instruction, Vol.2-4-337
Shared resources
mapping of, Vol.3-8-33
Shift instructions, Vol.2-4-339
SHL instruction, Vol.1-7-10, Vol.2-4-339
SHLD instruction, Vol.1-7-12, Vol.2-4-359
SHR instruction, Vol.1-7-11, Vol.2-4-339
SHRD instruction, Vol.1-7-12, Vol.2-4-362
Shuffle instructions
SSE extensions, Vol.1-10-9
SSE2 extensions, Vol.1-11-7
SHUFPD instruction, Vol.1-11-7, Vol.2-4-365
SHUFPS instruction, Vol.2-4-368
Shutdown
resulting from double fault, Vol.3-6-29
resulting from out of IDT limit condition, Vol.3-6-29
SI register, Vol.1-3-12
SIB byte, Vol.2-2-3
32-bit addressing forms of, Vol.2-2-7, Vol.2-2-20
description of, Vol.2-2-3
SIDT instruction, Vol.2-4-357, Vol.2-4-371, Vol.3-2-22, Vol.3-3-16, Vol.3-6-9
Signaling NaN (see SNaN)
Signed
infinity, Vol.1-4-15
integers, description of, Vol.1-4-4
integers, encodings, Vol.1-4-4
zero, Vol.1-4-14
Significand, extracting from floating-point number, Vol.2-3-390
Significand, of floating-point number, Vol.1-4-11
Sign, floating-point number, Vol.1-4-11
SIMD floating-point exception (#XM), Vol.1-11-18, Vol.3-2-18, Vol.3-6-48, Vol.3-9-8
SIMD floating-point exceptions
denormal operand exception (#D), Vol.1-11-15
description of, Vol.3-6-48, Vol.3-13-5
divide-by-zero (#Z), Vol.1-11-15
exception conditions, Vol.1-11-14
exception handlers, Vol.1-E-1
handler, Vol.3-13-3
inexact result exception (#P), Vol.1-11-16
invalid operation exception (#I), Vol.1-11-14
list of, Vol.1-11-13
numeric overflow exception (#O), Vol.1-11-15
numeric underflow exception (#U), Vol.1-11-16
precision exception (#P), Vol.1-11-16
software handling, Vol.1-11-18
summary of, Vol.1-C-1
support for, Vol.3-2-18
writing exception handlers for, Vol.1-E-1
SIMD floating-point exceptions, unmasking, effects of, Vol.2-3-472, Vol.2-4-289, Vol.2-4-558
SIMD floating-point flag bits, Vol.1-10-4
SIMD floating-point mask bits, Vol.1-10-4
SIMD floating-point rounding control field, Vol.1-10-4
SIMD (single-instruction, multiple-data)
execution model, Vol.1-2-2, Vol.1-2-3, Vol.1-9-4
instructions, Vol.1-2-15, Vol.1-5-17, Vol.1-10-7
MMX instructions, Vol.1-5-12
operations, on packed double-precision floating-point operands, Vol.1-11-4
operations, on packed single-precision floating-point operands, Vol.1-10-6
packed data types, Vol.1-4-8
SSE instructions, Vol.1-5-14
SSE2 instructions, Vol.1-11-4, Vol.1-12-2, Vol.1-12-6
Sine, x87 FPU operation, Vol.1-8-21, Vol.2-3-351, Vol.2-3-353
Single-precision floating-point format, Vol.1-4-4
Single-stepping
breakpoint exception condition, Vol.3-17-9
on branches, Vol.3-17-13
on exceptions, Vol.3-17-13
on interrupts, Vol.3-17-13
TF (trap) flag, EFLAGS register, Vol.3-17-9

SINIT, Vol.2-5-4
SLDT instruction, Vol.2-4-373, Vol.3-2-22

intermixing packed and scalar floating-point and 128-bit SIMD integer
instructions and data, Vol.1-11-22
introduction of into the IA-32 architecture, Vol.3-22-3
invalid operation exception (#I), Vol.1-11-14
logical instructions, Vol.1-11-7
masked responses to invalid arithmetic operations, Vol.1-11-14
memory ordering instructions, Vol.1-11-12
MMX technology compatibility, Vol.1-11-3
numeric overflow exception (#O), Vol.1-11-15
numeric underflow exception (#U), Vol.1-11-16
overview of, Vol.1-11-1
packed 128-Bit SIMD data types, Vol.1-4-8
packed and scalar floating-point instructions, Vol.1-11-4
programming environment, Vol.1-11-2
providing exception handlers for, Vol.3-13-4, Vol.3-13-5
providing operating system support for, Vol.3-13-1
QNaN floating-point indefinite, Vol.1-4-17
restoring SSE and SSE2 state, Vol.1-11-20
REX prefixes, Vol.1-11-3
saving and restoring state, Vol.3-13-6
saving SSE and SSE2 state, Vol.1-11-20
saving state on task, context switches, Vol.3-13-6
saving XMM register state on a procedure or function call, Vol.1-11-23
shuffle instructions, Vol.1-11-7
SIMD floating-point exception conditions, Vol.1-11-14
SIMD floating-point exception cross reference, Vol.1-C-5
SIMD Floating-point exception (#XM), Vol.3-6-48
SIMD floating-point exception (#XM), Vol.1-11-17, Vol.1-11-18
SIMD floating-point exceptions, Vol.1-11-13
SSE and SSE2 conversion instruction chart, Vol.1-11-9
SSE compatibility, Vol.1-11-3
SSE2 feature flag, CPUID instruction, Vol.1-11-19
system programming, Vol.1-13-17
unpack instructions, Vol.1-11-7
updating MMX technology routines using 128-bit SIMD integer
instructions, Vol.1-11-24
using TS flag to control saving state, Vol.3-13-7
writing applications with, Vol.1-11-19
x87 FPU compatibility, Vol.1-11-3
SSE2 feature flag
CPUID instruction, Vol.3-13-2

SSE2 feature flag, CPUID instruction, Vol.1-11-19, Vol.1-12-5
SSE2 instructions
descriptions of, Vol.1-11-4, Vol.1-12-2, Vol.1-12-6
SIMD floating-point exception cross-reference, Vol.1-C-5
summary of, Vol.1-5-17
SSE3
CPUID flag, Vol.2-3-192
SSE3 extensions
64-bit mode, Vol.1-12-1
asymmetric processing, Vol.1-12-1
checking for with CPUID, Vol.3-13-2
compatibility mode, Vol.1-12-1
CPUID feature flag, Vol.3-9-8
CPUID flag, Vol.2-3-192
DNA exceptions, Vol.1-12-9
EM flag, Vol.3-2-16
emulation, Vol.1-12-10
emulation of, Vol.3-13-6
enabling support in a system executive, Vol.1-12-5, Vol.1-12-19
event mgmt instruction encodings, Vol.2-B-59
example verifying SS3 support, Vol.3-8-43, Vol.3-8-47, Vol.3-14-2
exceptions, Vol.1-12-9
facilities for automatic saving of state, Vol.3-13-6, Vol.3-13-7
floating-point instruction encodings, Vol.2-B-59
guideline for packed addition/subtraction instructions, Vol.1-12-6
horizontal addition/subtraction instructions, Vol.1-12-4
horizontal processing, Vol.1-12-1
initialization, Vol.3-9-8
instruction that addresses cache line splits, Vol.1-5-20
instruction that improves X87-FP integer conversion, Vol.1-5-20
instructions for horizontal addition/subtraction, Vol.1-5-21
instructions for packed addition/subtraction, Vol.1-5-21
instructions that enhance LOAD/MOVE/DUPLICATE, Vol.1-5-21
instructions that improve synchronization between agents, Vol.1-5-21
integer instruction encodings, Vol.2-B-60
introduction of into the IA-32 architecture, Vol.3-22-3
LOAD/MOVE/DUPLICATE enhancement instructions, Vol.1-12-3
MMX technology compatibility, Vol.1-12-1
numeric error flag and IGNNE#, Vol.1-12-9
packed addition/subtraction instructions, Vol.1-12-4
programming environment, Vol.1-12-1
providing exception handlers for, Vol.3-13-4, Vol.3-13-5
providing operating system support for, Vol.3-13-1
REX prefixes, Vol.1-12-1
saving and restoring state, Vol.3-13-6
saving state on task, context switches, Vol.3-13-6
SIMD floating-point exception cross reference, Vol.1-C-7, Vol.1-C-8
specialized 120-bit load instruction, Vol.1-12-3
SSE compatibility, Vol.1-12-1
SSE2 compatibility, Vol.1-12-1
system programming, Vol.1-13-17
using TS flag to control saving of state, Vol.3-13-7
x87 FPU compatibility, Vol.1-12-1
SSE3 feature flag
CPUID instruction, Vol.3-13-2
SSE3 instructions
descriptions of, Vol.1-12-2
SIMD floating-point exception
cross-reference, Vol.1-C-7, Vol.1-C-8
summary of, Vol.1-5-20
SSSE3 extensions, Vol.2-B-60, Vol.2-B-66, Vol.2-B-73
64-bit mode, Vol.1-12-1
asymmetric processing, Vol.1-12-1
checking for support, Vol.1-12-9
compatibility, Vol.1-12-1
compatibility mode, Vol.1-12-1
CPUID flag, Vol.2-3-192
data types, Vol.1-12-1
DNA exceptions, Vol.1-12-9
emulation, Vol.1-12-10
enabling support in a system executive, Vol.1-12-9
exceptions, Vol.1-12-9
horizontal add/subtract instructions, Vol.1-12-7
horizontal processing, Vol.1-12-1
MMX technology compatibility, Vol.1-12-1
multiply and add packed instructions, Vol.1-12-8
numeric error flag and IGNNE#, Vol.1-12-9
packed absolute value instructions, Vol.1-12-7
packed align instruction, Vol.1-12-8
packed multiply high instructions, Vol.1-12-8
packed shuffle instruction, Vol.1-12-8
programming environment, Vol.1-12-1
SSSE2 compatibility, Vol.1-12-1
x87 FPU compatibility, Vol.1-12-1
SSSE3 instructions
descriptions of, Vol.1-12-6
summary of, Vol.1-5-21
Stack
64-bit mode, Vol.1-3-5, Vol.1-6-4
64-bit mode behavior, Vol.1-6-14
address-size attribute, Vol.1-6-3
alignment, Vol.1-6-2
alignment of stack pointer, Vol.1-6-2
current stack, Vol.1-6-1, Vol.1-6-3
description of, Vol.1-6-1
EIP register (return instruction pointer), Vol.1-6-3
maximum size, Vol.1-6-1
number allowed, Vol.1-6-1
overview of, Vol.1-3-4
passing parameters on, Vol.1-6-5
popping values from, Vol.1-6-1
procedure linking information, Vol.1-6-3
pushing values on, Vol.1-6-1
return instruction pointer, Vol.1-6-3
SS register, Vol.1-6-1
stack segment, Vol.1-3-14, Vol.1-6-1
stack-frame base pointer, EBP register, Vol.1-6-3
switching
on calls to interrupt and exception handlers, Vol.1-6-11
on inter-privilege level calls, Vol.1-6-8, Vol.1-6-12
privilege levels, Vol.1-6-7
width, Vol.1-6-2
Stack fault exception (#SS), Vol.3-6-36
Stack fault, x87 FPU, Vol.3-22-8, Vol.3-22-12
Stack pointers
privilege level 0, 1, and 2 stacks, Vol.3-7-5
size of, Vol.3-3-11
Stack segments
paging of, Vol.3-2-6
privilege level check when loading SS register, Vol.3-5-10
size of stack pointer, Vol.3-3-11
Stack switching
exceptions/interrupts when switching stacks, Vol.3-6-7
IA-32e mode, Vol.3-6-18
inter-privilege level calls, Vol.3-5-17
Stack-fault exception (#SS), Vol.3-22-33
Stacks
error code pushes, Vol.3-22-31
faults, Vol.3-6-36
for privilege levels 0, 1, and 2, Vol.3-5-17
interlevel RET/IRET
from a 16-bit interrupt or call gate, Vol.3-22-32
interrupt stack table, 64-bit mode, Vol.3-6-19
management of control transfers for
16- and 32-bit procedure calls, Vol.3-21-4
operation on pushes and pops, Vol.3-22-31
pointers to in TSS, Vol.3-7-5
stack switching, Vol.3-5-17, Vol.3-6-18
usage on call to exception
or interrupt handler, Vol.3-22-32
Stack, pushing values on, Vol.2-4-271
Stack, x87 FPU
stack fault, Vol.1-8-6
stack overflow and underflow exception (#IS), Vol.1-8-4, Vol.1-8-27

Status flags
EFLAGS register, Vol.1-3-16, Vol.1-8-6, Vol.1-8-7, Vol.1-8-20
Status flags, EFLAGS register, Vol.2-3-141, Vol.2-3-143, Vol.2-3-293, Vol.2-3-298, Vol.2-3-456, Vol.2-4-354, Vol.2-4-416
STC instruction, Vol.1-3-16, Vol.1-7-21, Vol.2-4-384
STD instruction, Vol.1-3-17, Vol.1-7-21, Vol.2-4-385
Stepping information, Vol.2-3-200
Stepping information, following processor initialization or reset, Vol.3-9-4
STI instruction, Vol.1-7-22, Vol.1-17-3, Vol.2-4-386, Vol.3-6-7
Sticky bits, Vol.1-8-5
STMXCSR instruction, Vol.1-10-12, Vol.1-11-24, Vol.2-4-388
Store buffer
caching terminology, Vol.3-11-5
characteristics of, Vol.3-11-4
description of, Vol.3-11-5, Vol.3-11-20
in IA-32 processors, Vol.3-22-33
location of, Vol.3-11-1
operation of, Vol.3-11-20
STOS instruction, Vol.1-3-17, Vol.1-7-19, Vol.2-4-307, Vol.2-4-389
STOSB instruction, Vol.2-4-389
STOSD instruction, Vol.2-4-389
STOSQ instruction, Vol.2-4-389
STOSW instruction, Vol.2-4-389
STPCLK# pin, Vol.3-6-3
STR instruction, Vol.2-4-393, Vol.3-2-22, Vol.3-3-16, Vol.3-7-7
Streaming SIMD extensions 2 (see SSE2 extensions)
Streaming SIMD extensions (see SSE extensions)
String data type, Vol.1-4-8
String instructions, Vol.2-3-158, Vol.2-3-421, Vol.2-3-492, Vol.2-3-583, Vol.2-4-19, Vol.2-4-349, Vol.2-4-389
Strong uncached (UC) memory type
description of, Vol.3-11-6
effect on memory ordering, Vol.3-8-16
use of, Vol.3-9-7, Vol.3-11-8
ST(0), top-of-stack register, Vol.1-8-3
Sub C-state, Vol.3-14-19
SUB instruction, Vol.1-7-8, Vol.2-3-22, Vol.2-3-253, Vol.2-3-490, Vol.2-4-395, Vol.3-8-3
SUBPD instruction, Vol.2-4-397
SUBSS instruction, Vol.2-4-402
Superscalar microarchitecture
P6 family microarchitecture, Vol.1-2-2
P6 family processors, Vol.1-2-7
Pentium 4 processor, Vol.1-2-9
Pentium Pro processor, Vol.1-2-2
Pentium processor, Vol.1-2-2
Supervisor mode
description of, Vol.3-5-28
U/S (user/supervisor) flag, Vol.3-5-28
SVR (spurious-interrupt vector register), local APIC, Vol.3-10-8, Vol.3-22-27
SWAPGS instruction, Vol.2-4-403, Vol.3-2-7, Vol.3-31-15
SYSCALL instruction, Vol.2-4-405, Vol.3-2-7, Vol.3-5-22, Vol.3-31-15
SYSENTER instruction, Vol.2-4-407, Vol.3-3-9, Vol.3-5-10, Vol.3-5-20, Vol.3-5-21, Vol.3-31-15, Vol.3-31-16
CPUID flag, Vol.2-3-195
SYSENTER_CS_MSR, Vol.3-5-21
SYSENTER_EIP_MSR, Vol.3-5-21
SYSENTER_ESP_MSR, Vol.3-5-21
SYSEXIT instruction, Vol.2-4-410, Vol.3-3-9, Vol.3-5-10, Vol.3-5-20, Vol.3-5-21, Vol.3-31-15, Vol.3-31-16
CPUID flag, Vol.2-3-195
SYSRET instruction, Vol.2-4-413, Vol.3-2-7, Vol.3-5-22, Vol.3-31-15
System
architecture, Vol.3-2-1, Vol.3-2-2
data structures, Vol.3-2-2
instructions, Vol.3-2-7, Vol.3-2-20
registers in IA-32e mode, Vol.3-2-7
registers, introduction to, Vol.3-2-6
segment descriptor, layout of, Vol.3-5-2
segments, paging of, Vol.3-2-6
System management mode (see SMM)
System programming
MMX technology, Vol.3-12-1
SSE/SSE2/SSE3 extensions, Vol.1-13-17
virtualization of resources, Vol.3-32-1
System-management mode (see SMM)

T

T (debug trap) flag, TSS, Vol.3-7-5
Tangent, x87 FPU operation, Vol.1-8-21, Vol.2-3-341
Task gate, Vol.1-6-13
Task gates
descriptor, Vol.3-7-8
executing a task, Vol.3-7-2
handling a virtual-8086 mode interrupt or exception through, Vol.3-20-14
IA-32e mode, Vol.3-2-5
in IDT, Vol.3-6-10
introduction for IA-32e, Vol.3-2-4
introduction to, Vol.3-2-4, Vol.3-2-5
layout of, Vol.3-6-10
referencing of TSS descriptor, Vol.3-6-14
Task management, Vol.3-7-1
data structures, Vol.3-7-3
mechanism, description of, Vol.3-7-2
Task register, Vol.1-3-4, Vol.3-3-16
description of, Vol.3-2-13, Vol.3-7-1, Vol.3-7-7
IA-32e mode, Vol.3-2-13
initializing, Vol.3-9-10
introduction to, Vol.3-2-6
loading, Vol.2-3-500
storing, Vol.2-4-393
Task state segment (see TSS)
Task switch
CALL instruction, Vol.2-3-114
return from nested task, IRET instruction, Vol.2-3-446
Task switching
description of, Vol.3-7-3
exception condition, Vol.3-17-10
operation, Vol.3-7-10
preventing recursive task switching, Vol.3-7-13
saving MMX state on, Vol.3-12-4
saving SSE/SSE2/SSE3 state on task or context switches, Vol.3-13-6
T (debug trap) flag, Vol.3-7-5
Tasks
address space, Vol.3-7-14
description of, Vol.3-7-1
exception handler, Vol.1-6-13
exception-handler task, Vol.3-6-11
executing, Vol.3-7-2
Intel 286 processor tasks, Vol.3-22-36
interrupt handler, Vol.1-6-13
interrupt-handler task, Vol.3-6-11
